## British Library Cataloguing in Publication Data

A catalogue record for this book is available from the British I ibrary
ISBN 047085006 X (Cloth)
ISBN 0470850078 (Рарег)
Produced from camera ready copy supplied by the author.
Printed and bound in Great Britain by Antony Rowe Ltd, Chippenham, Wiltshire.
This book is printed on acid-free paper responsibly manufactured from sustainable forestry in which at least two trees are planted for each one used for paper production.

The cover shows the ${ }^{13} \mathrm{C}$ NMR spectrum of $\alpha$ - and $\beta$-D-xylopyranose at mutarotational equilibrium ( $35 \% \alpha$, $65 \% \beta$, in deuterium oxide, $100 \mathrm{MHz},{ }^{l} H$ broadband decoupling) with the CC INADEQUATE contour plot. An interpretation of the plot according to principles described in Section 2.2.7 gives the CC bonds of the two isomers and confirms the assignment of the signals in Table 2.12.

## Preface

Virtually, all students of chemistry, biochemistry, pharmacy and related subjects learn how to deduce molecular structures from nuclear magnetic resonance (NMR) spectra. Undergraduate examinations routinely set problems using NMR spectra, and masters' and doctoral theses describing novel synthetic or natural products provide many examples of how powerful NMR has become in structure elucidation. Existing texts on NMR spectroscopy generally deal with the physical background of the newer and older techniques as well as the relationships between NMR parameters and chemical structures. Very few, however, convey the know-how of structure determination using NMR, namely the strategy and methodology by which molecular structures are deduced from NMR spectra.
This book, based on many lectures and seminars, attempts to provide advanced undergraduates and graduate students with a systematic, readable and inexpensive introduction to the methods of structure determination by NMR. Chapter 1 starts with a deliberately concise survey of the basic terms, parameters and techniques dealt with in detail in other books, which cover the basic principles of NMR, pulse sequences as well as theoretical aspects of chemical shifts and spin-spin coupling, and which this workbook is not intended to replace. An introduction to basic strategics and tactics of structure determination using one- and two-dimensional NMR methods then follows in Chapter 2. Here, the emphasis is always on how spectra and associated parameters can be used to identify structural fragments. This chapter presents those topics that are essential for the identification of compounds or for solving structures, including atom connectivities, relative configuration and conformation, intra- and intermolecular interactions and, in some cases, molecular dynamics. Following the principle of 'learning by doing', Chapter 3 presents a series of case studies, providing spectroscopic details of 55 compounds that illustrate typical applications of NMR techniques in the structural characterisation of both synthetic and natural products. The level of difficulty, the sophistication of the methodology required increases from question to question, so that all readers will be able to find material suited to their knowledge and ability. One can work independently, solve the problem from the spectra and check the result in the formula index, or follow the detailed solutions given in Chapter 4. The spectroscopic details are presented in a way that makes the maximum possible information available at a glance, requiring minimal page turning. Chemical shifts and coupling constants do not have to be read off from scales but are presented numerically, allowing the reader to concentrate directly on problem solving without the need for tedious routine work.
Actual methods of two dimensional NMR such as some inverse techniques of heteronuclear shift correlation experiments (HMQC, HSQC, HMBC), proton shift correlations (TOCSY) and twodimensional detection of nuclear Overhauser effects (ROESY) are illustrated in Chapter 2 of this edition. New problems are added in Chapter 3 and 4 not only to replace some of the former ones but also in order to improve the quality and to demonstrate some applications of the actual methods shown in Chapter 2. All formulae have been redrawn using new software; all spectra have been scanned into the data file and the layout has been optimized. My thanks must go to Dr. Rudolf Hartmann for recording some of the two-dimensional NMR experiments, to Klaus Rotscheidt for scanning and his assistance in electronic editing, and especially to Julia Wade for having translated the original German text for the first English edition of this book.

Eberhard Breitmaier

## Symbols and Abbreviations

APT: Attached proton test, a modification of the $J$-modulated spin-echo experiment to determine CH multiplicities, a less sensitive alternative to DEPT

CH COLOC: Correlation via long-range CH coupling, detects CH connectivities through two or three (more in a few cases) bonds in the CH COSY format, permits localisation of carbon nuclei two or three bonds apart from an individual proton

COSY: Correlated spectroscopy, two-dimensional shift correlations via spin-spin coupling, homonuclear (e.g. $H H$ ) or heteronuclear (e.g. CH )

CH COSY: Correlation via one-bond CH coupling, also referred to as HETCOR (heteronuclear shift correlation), provides carbon-13- and proton shifts of nuclei in CH bonds as cross signals in a $\delta_{\mathrm{C}}$ versus $\delta_{H}$ diagram, assigns all $\mathrm{C} H$ bonds of the sample
$H H$ COSY: Correlation via $H H$ coupling which has square symmetry because of equal shift scales in both dimensions ( $\delta_{H}$ versus $\delta_{H}$ ) provides all detectable $H H$ connectivities of the sample

CW: Continuous wave or frequency sweep, the older, less sensitive, more time consuming basic technique of NMR detection

DEPT: Distortionless enhancement by polarisation transfer, differentiation between $\mathrm{CH}, \mathrm{CH}_{2}$ and $\mathrm{CH}_{3}$ by positive $\left(\mathrm{CH}, \mathrm{CH}_{3}\right)$ or negative $\left(\mathrm{CH}_{2}\right)$ signal amplitudes, using improved sensitivity of polarisation transfer

FID: Frce induction decay, decay of the induction (transverse magnetisation) back to equilibrium (transverse magnetisation zero) due to spin-spin relaxation, following excitation of a nuclear spin by a radio frequency pulse, in a way which is free from the influence of the radiofrequency field; this signal (time-domain) is Fourier-transformed to the FT NMR spectrum (frequency domain)

FT NMR: Fourier transform NMR, the newer and more sensitive, less time consuming basic technique of NMR detection, almost exclusively used

INADEQUATE: Incredible natural abundance double quantum transfer experiment, segregates AB or AX systems due to homonuclear one-bond couplings of less abundant nuclei, e.g. ${ }^{13} \mathrm{C}-{ }^{13} \mathrm{C}$; CC INADEQUATE detects CC bonds (carbon skeleton) present in the sample

HMBC: Heteronuclear multiple bond correlation, inverse $\mathrm{C} I I$ corrclation via long-range $\mathrm{C} H$ coupling, same format and information as described for $\left({ }^{13} \mathrm{C}\right.$ detected) $\mathrm{C} H$ COLOC but much more sensitive (therefore less time-consuming) because of ${ }^{1} H$ detection

HMQC: Heteronuclear multiple quantum coherence, e.g. inverse CH correlation via one-bond carbon proton-coupling, same format and information as described for $\left({ }^{13} \mathrm{C}\right.$ detected) CH COSY but much more sensitive (therefore less time-consuming) because of ${ }^{1} H$ detection

HSQC: Heteronuclear single quantum coherence, e.g. inverse CH correlation via one-bond coupling providing the same result as HMQC but using an alternative pulse sequence

NOE: Nuclear Overhauser effect, change of signal intensities (integrals) during decoupling experiments decreasing with spatial distance of nuclei

NOESY: Nuclear Overhauser effect spectroscopy, detection of NOE in the $H H$ COSY square format, traces out closely spaced protons in larger molecules

ROESY: Rotating frame NOESY, detection of NOE in the $H H$ COSY format with suppressed spin-diffusion, detects closely spaced protons also in smaller molecules

TOCSY: Total correlation spectroscopy, in the homonuclear COSY format, e.g. $H H$ TOCSY traces out all proton-proton connectivities of a partial structure in addition to the connectivities ( ${ }^{2} \mathrm{~J}$, ${ }^{3} J,{ }^{4} J,{ }^{5} J$ as detected by $H H$ COSY
$J$ or ${ }^{1} J$ : nuclear spin-spin coupling constant (in Hz ) through one bond (one-bond coupling)
${ }^{2} J,{ }^{3} J,{ }^{4} J,{ }^{5} J$, nuclear spin-spin coupling constant (in Hz) through two, three, four and five bonds (geminal, vicinal, longer-range couplings)

Multiplet abbreviations:

| S, s | $:$ | singlet |
| :--- | :--- | :--- |
| D, d | $:$ | doublet |
| T, t | $:$ | triplet |
| Q, q | $:$ | quartet |
| Qui, qui | $:$ | quintet |
| Sxt, sxt | $:$ | sextet |
| Sep, sep | $:$ | septet |
| o | $:$ | overlapping |
| b | $:$ | broad |

Capital letters: multiplets which are the result of coupling through one hond
Lower case letters: multiplets which are the result of coupling through more bonds than one
$\delta_{I I}, \delta_{\mathrm{C}}, \delta_{\mathrm{N}} \quad: \quad$ Proton, carbon-13 and nitrogen- 15 chemical shifts
Contrary to IUPAC conventions, chemical shifts $\delta$ in this book are scaled in ppm in the spectra, thus enabling the reader to differentiate at all times between shift values (ppm) and coupling constants (Hz); ppm (parts per million) is in this case the ratio of two frequencies of different orders of magnitude, $\mathrm{Hz} / \mathrm{MHz}=1: 10^{6}$ without physical dimension

Italicised data and multiplet abbreviations refer to ${ }^{I} H$ in this book

## 1 SHORT INTRODUCTION TO BASIC PRINCIPLES AND METHODS

### 1.1 Chemical shift

Chemical shift relates the Larmor frequency of a nuclear spin to its chemical environment ${ }^{1-3}$. The Larmor frequency is the precession frequency $v_{0}$ of a nuclear spin in a static magnetic field (Fig. 1.1). This frequency is proportional to the flux density $B_{0}$ of the magnetic field ( $v_{0} / B_{0}=$ const. $)^{1-3}$. It is convenient to reference the chemical shift to a standard such as tetramethylsilane [TMS, $\left(\mathrm{CH}_{3}\right)_{4} \mathrm{Si}$ ] rather than to the proton $\mathrm{H}^{+}$. Thus, a frequency difference $(\mathrm{Hz})$ is measured for a proton or a carbon- 13 nucleus of a sample from the ${ }^{1} H$ or ${ }^{13} \mathrm{C}$ resonance of TMS. This value is divided by the absolute value of the Larmor frequency of the standard (e.g. 400 MHz for the protons and 100 MHz for the carbon- 13 nuclei of TMS when using a 400 MHz spectrometer), which itself is proportional to the strength $B_{0}$ of the magnetic field. The chemical shift is therefore given in parts per million (ppm, $\delta$ scale, $\delta_{H}$ for protons, $\delta_{\mathrm{C}}$ for carbon-13 nuclei), because a frequency difference in Hz is divided by a frequency in MHz , these values being in a proportion of $1: 10^{6}$.

Figure 1.1. Nuclear precession: nuclear charge and nuclear spin give rise to a magnetic moment of nuclei such as protons and carbon-13. The vector $\mu$ of the magnetic moment precesses in a static magnetic field with the Larmor frequency $v_{0}$ about the direction of the magnetic flux density vector $\boldsymbol{B}_{0}$

Chemical shift is principally caused by the electrons in the molecule having a shielding effect on the nuclear spin. More precisely, the electrons cause a shielding field which opposes the external magnetic field: the precession frequency of the nuclear spin (and in turn the size of its chemical shift) is therefore reduced. An atomic nucleus (e.g. a proton) whose shift is reduced is said to be shielded (high shielding field); an atom whose shift is increased is said to be deshielded (low shielding field). This is illustrated in Fig. 1.2 which also shows that NMiR spectra are presented with chemical shift and frequency decreasing from left to right.

### 1.2 Spin-spin coupling and coupling constants

Indirect or scalar coupling ${ }^{1-3}$ of nuclear spins through covalent bonds causes the splitting of NMR signals into multiplets in high-resolution NMR spectroscopy in the solution state. The direct or
dipolar coupling between nuclear spins through space is only observed for solid or liquid crystalline samples. In a normal solution such coupling is cancelled out by molecular motion.
The coupling constant for first-order spectra (see Section 1.4) is the frequency difference $J$ in Hz between two multiplet lines. Unlike chemical shift, the frequency value of a coupling constant does not depend on the strength of the magnetic field. In high-resolution NMR a distinction is made between coupling through one bond ( ${ }^{l} J$ or simply $J$, one-bond couplings) and coupling through several bonds, e.g. two bonds ( ${ }^{2} J$, geminal couplings), three bonds ( ${ }^{3} J$, vicinal couplings) or four or five bonds ( ${ }^{4} J$ and ${ }^{5} J$, long-range couplings). For example, the $\mathrm{CH}_{2}$ and $\mathrm{CH}_{3}$ protons of the ethyl group in ethyldichloroacetate (Fig. 1.2) are separated by three bonds; their (vicinal) coupling constant is ${ }^{3} J=7 \mathrm{~Hz}$.

Figure 1.2. ${ }^{1} \mathrm{H}$ NMR spectrum of ethyl dichloroacetate $\left(\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 80 \mathrm{MHz}\right.$ ). The proton of the $\mathrm{CHCl}_{2}$ group is less shielded (more strongly deshielded) in comparison with the protons of the $\mathrm{CH}_{2}$ and $\mathrm{CH}_{3}$ residues

### 1.3 Signal multiplicity (multiplets)

The signal multiplicity in first-order spectra (see Section 1.4) is the extent to which an NMR signal is split as a result of spin-spin coupling ${ }^{1 \cdot 3}$. Signals which show no splitting are denoted as singlets ( $s$ ). Those with two, three, four, five, six or seven lines are known as doublets (d), triplets ( $t$ ), quartets ( $q$, Figs 1.2 and 1.3), quintets (qui), sextets (sxt) and septets (sep), respectively, but only where the lines of the multiplet signal are of equal distance apart, and the one coupling constant is therefore shared by them all. Where two or three different coupling constants produce a multiplet, this is referred to as a two- or three-fold multiplet, respectively, e.g. a doublet of doublets (dd, Fig. 1.3), or a doublet of doublets of doublets (ddd, Fig. 1.3). If both coupling constants of a doublet of doublets are sufficiently similar $\left(J_{1} \sim J_{2}\right)$, the middle signals overlap, thus generating a 'pseudotriplet' (' $t$ ', Fig. 1.3).

The ${ }^{l} H$ NMR spectrum of ethyl dichloroacetate (Fig. 1.2), as an example, displays a triplet for the $\mathrm{CH}_{3}$ group (two vicinal H ), a quartet for the $\mathrm{OCH}_{2}$ group (three vicinal H ) and a singlet for the CHCl 2 fragment (no vicinal $H$ for coupling).

Figure 1.3. Quartet, doublet of doublets, pseudotriplet and threefold doublet (doublet of doublets of doublets)

### 1.4 Spectra of first and higher order

First-order spectra (multiplets) are observed when the coupling constant is small compared with the frequency difference of chemical shifts between the coupling nuclei ${ }^{2,3}$. This is referred to as an $A_{m} X_{n}$ spin system, where nucleus $A$ has the smaller and nucleus $X$ has the considerably larger chemical shift. An $A X$ system (Fig. 1.4) consists of an $A$ doublet and an $X$ doublet with the common coupling constant $J_{A X}$. The chemical shifts are measured from the centres of each doublet to the reference resonance.

Figure 1.4. Two-spin system of type $A X$ with a chemical shift difference which is large compared with the coupling constants (schematic)

| $n=0$ | Singlet |  |  |  |  |  |  | 1 |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | Doublet |  |  |  |  |  | 1 | : | 1 |  |  |  |  |  |
| 2 | Triplet |  |  |  |  | 1 | : | 2 | : | 1 |  |  |  |  |
| 3 | Quartet |  |  |  | 1 | : | 3 | : | 3 | : | 1 |  |  |  |
| 4 | Quintet |  |  | 1 | : | 4 | . | 6 | . | 4 | : | 1 |  |  |
| 5 | Sextet |  | 1 | : | 5 | . | 10 | : | 10 | : | 5 |  | 1 |  |
| 6 | Septet | 1 |  | 6 | : | 15 | : | 20 | : | 15 | : | 6 |  | 1 |

Figure 1.5. Relative intensities of first-order multiplets (Pascal triangle)

Multiplicity rules apply for first-order spectra ( $A_{m} X_{n}$ systems): When coupled, $n_{X}$ nuclei of an element $X$ with nuclear spin quantum number $I_{X}=1 / 2$ produce a splitting of the $A$ signal into $n_{X}+1$ lines; the relative intensities of the individual lines of a first-order multiplet are given by the coefficients of the Pascal triangle (Fig. 1.5). The protons of the ethyl group of ethyl dichloroacetate (Fig. 1.2) as examples give rise to an $A_{3} X_{2}$ system with the coupling constant ${ }^{3} J_{A X}=7 \mathrm{~Hz}$; the $A$ protons (with smaller shift) are split into a triplet (two vicinal protons $X, n_{X}+1=3$ ); the $X$ protons appear as a quartet because of three vicinal $A$ protons $\left(n_{A}+1=4\right)$. In general, for a given number, $n_{X}$, of coupled nuclear spins of spin quantum number $I_{X}$, the $A$ signal will be split into ( $2 n_{X} I_{X}+1$ ) multiplet lines (e.g. Fig. 1.9).
Spectra of greater complexity may occur for systems where the coupling constant is of similar magnitude to the chemical shift difference between the coupled nuclei. Such a case is referred to as an $A_{m} B_{n}$ system, where nucleus $A$ has the smaller and nucleus $B$ the larger chemical shift.
An $A B$ system (Fig. 1.6) consists, for example, of an $A$ doublet and a $B$ doublet with the common coupling constant $J_{A B}$, where the external signal of both doublets is attenuated and the internal signal is enhanced. This is referred to as an $A B$ effect, a 'roofing' symmetric to the centre of the $A B$ system ${ }^{2}$; 'roofing' is frequently observed in proton NMR spectra, even in practically first order spectra (Fig. 1.2, ethyl quartet and triplet). The chemical shifts $v_{A}$ and $v_{B}$ are displaced from the centres of the two doublets, approaching the frequencies of the more intense inner signals.

Figure 1.6. Two-spin system of type $A B$ with a small chemical shift difference compared to the coupling constant (schematic)

### 1.5 Chemical and magnetic equivalence

Chemical equivalence: atomic nuclei in the same chemical environment are chemically equivalent and thus show the same chemical shift. The $2,2^{\prime}$ - and $3,3^{\prime}$-protons of a 1,4 -disubstituted benzene ring, for example, are chemically equivalent because of molecular symmetry.

para coupling: $J_{A X}=0.5-1 \mathrm{~Hz}$

Magnetic equivalence: chemically equivalent nuclei are magnetically equivalent if they display the same coupling constants with all other nuclear spins of the molecule ${ }^{2,3}$. For example, the 2,2'-
$\left(A A^{\prime}\right)$ and $3,3^{\prime}-\left(X, X^{\prime}\right)$ protons of a 1,4-disubstituted benzene ring such as 4-nitroanisole are not magnetically equivalent, because the 2-proton $A$ shows an ortho coupling with the 3-proton $X\left({ }^{3} J=\right.$ $7-8 \mathrm{~Hz}$ ), but displays a different para coupling with the $3^{\prime}$-proton $X^{\prime}\left({ }^{5} J=0.5-1 \mathrm{~Hz}\right)$. This is therefore referred to as an $A A^{\prime} X X^{\prime}$ system (e.g. Fig. 2.6 c ) but not as an $A_{2} X_{2}$ or an $(A X)_{2}$ system. The ${ }^{\prime} H$ NMR spectrum in such a case can never be first-order, and the multiplicity rules do not apply. The methyl protons in ethyl dichloroacetate (Fig. 1.2), however, are chemically and magnetically equivalent because the ${ }^{3} J_{H H}$ coupling constants depend on the geometric relations with the $\mathrm{CH}_{2}$ protons and these average to the same for all $\mathrm{CH}_{3}$ protons due to rotation about the CC single bond; they are the $A_{3}$ part of an $A_{3} X_{2}$ system characterising an ethoxy group ( $\mathrm{CH}^{A}{ }_{3}-\mathrm{CH}^{X}{ }_{2}-\mathrm{O}-$ ) in ${ }^{l} H$ NMR.

### 1.6 Fourier transform (FT) NMR spectra

There are two basic techniques for recording high-resolution NMR spectra ${ }^{2-6}$. In the older $C W$ technique, the frequency or field appropriate for the chemical shift range of the nucleus (usually ${ }^{l} H$ ) is swept by a continuously increasing (or decreasing) radio-frequency. The duration of the sweep is long, typically $2 \mathrm{~Hz} / \mathrm{s}$, or 500 s for a sweep of 1000 Hz , corresponding to 10 ppm in 100 MHz proton NMR spectra. This monochromatic excitation therefore takes a long time to record.
In the FT technique, the whole of the Larmor frequency range of the observed nucleus is excited by a radiofrequency pulse. This causes transverse magnetisation to build up in the sample. Once excitation stops, the transverse magnetisation decays exponentially with the time constant $T_{2}$ of spin-spin relaxation provided the field is perfectly homogeneous. In the case of a one-spin system, the corresponding NMR signal is observed as an exponentially decaying alternating voltage (free induction decay, FID); multi-spin systems produce an interference of several exponentially decaying alternating voltages, the pulse interferogram (Fig. 1.7).The frequency of each alternating voltage is the difference between the individual Larmor frequency of one specific kind of nucleus and the frequency of the exciting pulse. The Fourier transformation (FT) of the pulse interferogram produces the Larmor frequency spectrum; this is the FT NMR spectrum of the type of nucleus being observed. Fourier transformation involving the calculation of all Larmor frequencies contributing to the interferogram is performed with the help of a computer within a time of less than 1 s .

Figure 1.7. Pulse interferogram and $\mathrm{FT}{ }^{13} \mathrm{C}$ NMR spectrum of glycerol, $\left(\mathrm{DOCH}_{2}\right)_{2} \mathrm{CHOD},\left[\mathrm{D}_{2} \mathrm{O}, 25^{\circ} \mathrm{C}, 100 \mathrm{MHz}\right.$ ]

The main advantage of the $F T$ technique is the short time required for the procedure (about 1 s per interferogram). Within a short time a large number of individual interferograms can be accumulated, thus averaging out electronic noise (FID accumulation), and making the FT method the preferred approach for less sensitive NMR probes involving isotopes of low natural abundance $\left({ }^{13} \mathrm{C}\right.$, ${ }^{15} \mathrm{~N}$ ). All of the spectra in this book with the exception of those in Figs. 1.8, 2.19 and 2.25 are $F T$ NMR spectra.

### 1.7 Spin decoupling

Spin decoupling (double resonance) ${ }^{2,3,5,6}$ is an NMR technique in which, to take the simplest example, an $A X$ system, the splitting of the $A$ signal due to $J_{A X}$ coupling is removed if the sample is irradiated strong enough by a second radiofrequency which resonates with the Larmor frequency of the $X$ nucleus. The $A$ signal then appears as a singlet; at the position of the $X$ signal interference is observed between the $X$ Larmor frequency and the decoupling frequency. If the $A$ and $X$ nuclei are the same isotope (e.g. protons), this is referred to as selective homonuclear decoupling. If $A$ and $X$ are different, e.g. carbon-13 and protons, then it is referred to as heteronuclear decoupling.
Figure 1.8 illustrates homonuclear decoupling experiments with the CH protons of 3-aminoacrolein. These give rise to an $A M X$ system (Fig. 1.8a). Decoupling of the aldehyde proton $X$ (Fig. $1.8 \mathbf{b}$ ) simplifies the NMR spectrum to an $A M$ system ( ${ }^{3} J_{A M}=12.5 \mathrm{~Hz}$ ); decoupling of the $M$ proton (Fig. 1.8c) simplifies to an $A X$ system ( ${ }^{3} J_{A X}=9 \mathrm{~Hz}$ ). These experiments reveal the connectivities of the protons within the molecule.

Figure 1.8. Homonuclear decoupling of the CH protons of 3 -aminoacrolein $\left(\mathrm{CD}_{3} \mathrm{OD}, 25^{\circ} \mathrm{C}, 90 \mathrm{MHz}\right)$. (a) ${ }^{1} \mathrm{H}$ NMR spectrum; (b) decoupling at $\delta_{H}=8.5$; (c) decoupling at $\delta_{H}=7.3$. At the position of the decoupled signal in (b) and (c) interference beats are observed because of the superposition of the two very similar frequencies

In ${ }^{13} \mathrm{C}$ NMR spectroscopy, three kinds of heteronuclear spin decoupling are used ${ }^{5,6}$. In proton broadband decoupling of ${ }^{13} \mathrm{C}$ NMR spectra, decoupling is carried out unselectively across a frequency range which encompasses the whole range of the proton shifts. The spectrum then displays up to $n$ singlet signals for the $n$ non-equivalent C atoms of the molecule.
Figures $1.9 \mathbf{a}$ and $\mathbf{b}$ demonstrate the effect of proton broadband decoupling in the ${ }^{13} \mathrm{C}$ NMR spectrum of a mixture of ethanol and hexadeuterioethanol. The $\mathrm{CH}_{3}$ and $\mathrm{CH}_{2}$ signals of ethanol appear as intense singlets upon proton broadband decoupling whilc the $\mathrm{CD}_{3}$ and $\mathrm{CD}_{2}$ resonances of the deuteriated compound still display their septet and quintet fine structure; deuterium nuclei are not affected by ${ }^{l} H$ decoupling because their Larmor frequencies are far removed from those of protons; further, the nuclear spin quantum number of deuterium is $I_{D}=1$; in keeping with the general multiplicity rule ( $2 n_{X} I_{X}+1$, Section 1.4), triplets, quintets and septets are observed for $\mathrm{CD}, \mathrm{CD}_{2}$ and $\mathrm{CD}_{3}$ groups, respectively. The relative intensities in these multiplets do not follow Pascal's triangle (1:1:1 triplet for CD ; 1:3:4:3:1 quintet for $\mathrm{CD}_{2} ; 1: 3: 6: 7: 6: 3: 1$ septet for $\mathrm{CD}_{3}$ ).

Figure 1.9. ${ }^{13} \mathrm{C}$ NMR spectra of a mixture of ethanol and hexadeuterioethanol [27:75 v/v, $\left.25^{\circ} \mathrm{C}, 20 \mathrm{MHz}\right] .(\mathrm{a}){ }^{1} \mathrm{H}$ broadband decoupled; (b) without decoupling. The deuterium isotope effect $\delta_{C H}-\delta_{C D}$ on ${ }^{13} \mathrm{C}$ chemical shifts is 1.1 and 0.05 ppm for methyl and metitylene caribon nuciei, respectively

In selective proton decoupling of ${ }^{13} \mathrm{C}$ NMR spectra, decoupling is performed at the precession frequency of a specific proton. As a result, a singlet only is observed for the attached C atom. Offresonance conditions apply to the other C atoms. For these the individual lines of the CH multiplets move closer together, and the relative intensities of the multiplet lines change from those given by the Pascal triangle; external signals are attenuated whereas internal signals are enhanced.

Selective ${ }^{l} H$ decoupling of ${ }^{13} \mathrm{C}$ NMR spectra was used for assignment of the CH connectivities ( CH bonds) before the much more efficient two-dimensional CH shift correlation experiments (see Section 2.2.8) became routine. Off-resonance decoupling of the protons was helpful in determining CH multiplicities before better methods became available (see Section 2.2.2). In pulsed or gated decoupling of protons (broadband decoupling only between FIDs), coupled ${ }^{13} \mathrm{C}$ NMR spectra are obtained in which the CH multiplets are enhanced by the nuclear Overhauser effect (NOE, see Section 1.8). This method is used when CH coupling constants are required for structure analysis because it enhances the multiplets of carbon nuclei attached to protons; the signals of quaternary carbons two bonds apart from a proton are also significantly enhanced. Figure 1.10 demonstrates this for the carbon nuclei in the 4,6-positions of 2,4,6-trichloropyrimidine.

Figure 1.10. ${ }^{13} \mathrm{C}$ NMR spectra of 2,4,6-trichloropyrimidine $\left[\mathrm{C}_{6} \mathrm{D}_{6}, 75 \% \mathrm{v} / \mathrm{v} 25^{\circ} \mathrm{C}, 20 \mathrm{MHz}\right]$. (a) ${ }^{13} \mathrm{C}$ NMR spectrum without proton decoupling; (b) NOE enhanced coupled ${ }^{13} \mathrm{C}$ NMR spectrum (gated decoupling)

### 1.8 Nuclear Overhauser effect

The nuclear Overhauser effect ${ }^{2,3}$ (NOE, also an abbreviation for nuclear Overhauser enhancement) causes the change in intensity (increase or decrease) during decoupling experiments. The maximum possible NOE in high-resolution NMR of solutions depends on the gyromagnetic ratio of the coupled nuclei. Thus, in the homonuclear case such as proton-proton coupling, the NOE is much less than 0.5 , whereas in the most frequently used heteronuclear example, proton decoupling of ${ }^{13} \mathrm{C}$ NMR spectra, it may reach 1.988 . Instead of the expected signal intensity of 1 , the net result is to increase the signal intensity threefold $(1+1.988)$. In proton broadband and gated decoupling of ${ }^{13} \mathrm{C}$ NMR spectra, NOE enhancement of signals by a factor of as much as 2 is routine, as was shown in Figs 1.9 and 1.10.

Quantitative analysis of mixtures is achieved by evaluating the integral steps of ${ }^{l} H$ NMR spectra. This is demonstrated in Fig. 1.11a for 2,4-pentanedione (acetylacetone) which occurs as an equilibrium mixture of $87 \%$ enol and $13 \%$ diketone.

Keto (oxo) tautomer K
Enol tautomer E

Figure 1.11. NMR analysis of the keto-enol tautomerism of 2,4-pentanedione $\left[\mathrm{CDCl}_{3}, 50 \% \mathrm{~V} / \mathrm{V}, 25{ }^{\circ} \mathrm{C}, 60 \mathrm{MHz}\right.$ for ${ }^{1} \mathrm{H}, 20 \mathrm{MHz}$ for ${ }^{13} \mathrm{C}$ ]. (a) ${ }^{7} \mathrm{H}$ NMR spectrum with integrals [result: keto: enol = 13:87]; (b) ${ }^{1} \mathrm{H}$ broadband decoupled ${ }^{13} \mathrm{C}$ NMR spectrum; (c) ${ }^{13} \mathrm{C}$ NMR spectrum obtained by inverse gated ${ }^{1} \mathrm{H}$ decoupling with integrals [result: keto: enol = $15: 85( \pm 1)$ ]

A similar evaluation of the ${ }^{13} \mathrm{C}$ integrals in ${ }^{l} H$ broadband decoupled ${ }^{13} \mathrm{C}$ NMR spectra fails in most cases because signal intensities are influenced by nuclear Overhauser enhancements and relaxation times and these are usually specific for each individual carbon nucleus within a molecule. As a result, deviations are large ( $81-93 \%$ enol) if the keto-enol equilibrium of 2,4-pentanedione is analysed by means of the integrals in the ${ }^{1} H$ broadband decoupled ${ }^{13} \mathrm{C}$ NMR spectrum (Fig. 1.11b). Inverse gated decoupling ${ }^{2,3}$, involving proton broadband decoupling only during the FIDs, helps to solve the problem. This technique provides ${ }^{1} H$ broadband decoupled ${ }^{13} \mathrm{C}$ NMR spectra with suppressed nuclear Overhauser effect so that signal intensities can be compared and keto-enol tautomerism of 2,4-pentanedione, for example, is analysed more precisely as shown in Fig. 1.11c.

### 1.9 Relaxation, relaxation times

Relaxation ${ }^{2,3,5}$ refcrs to all processes which regenerate the Boltzmann distribution of nuclear spins on their precession states and the resulting equilibrium magnetisation along the static magnetic field. Relaxation also destroys the transverse magnetisation arising from phase coherence of nuclear spins built up upon NMR excitation.
Spin-lattice relaxation is the steady (exponential) build-up or regeneration of the Boltzmann distribution (equilibrium magnetisation) of nuclear spins in the static magnetic field. The lattice is the molecular environment of the nuclear spin with which energy is exchanged.
The spin-lattice relaxation time, $T_{l}$, is the time constant for spin-lattice relaxation which is specific for every nuclear spin. In FT NMR spectroscopy the spin-lattice relaxation must 'keep pace' with the exciting pulses. If the sequence of pulses is too rapid, e.g. faster than $3 T_{/ \max }$ of the 'slowest' C atom of a molecule in carbon-13 resonance, a decrease in signal intensity is observed for the 'slow' C atom due to the spin-lattice relaxation getting 'out of step'. For this reason, quaternary C atoms can be recognised in carbon-13 NMR spectra by their weak signals.
Spin-spin relaxation is the steady decay of transverse magnetisation (phase coherence of nuclear spins) produced by the NMR excitation where there is perfect homogeneity of the magnetic field. It is evident in the shape of the FID (free induction decay), as the exponential decay to zero of the transverse magnetisation produced in the pulsed NMR experiment. The Fourier transformation of the FID signal (time domain) gives the FT NMR spectrum (frequency domain, Fig. 1.7).
The spin-spin relaxation time, $T_{2}$, is the time constant for spin-spin relaxation which is also specific for every nuclear spin (approximately the time constant of FID). For small- to medium-sized molecules in solution $T_{2} \sim T_{1}$. The value of $T_{2}$ of a nucleus deternines the widit of the appropriate NMR signal at half-height ('half-width') according to the uncertainty relationship. The smaller is $T_{2}$, the broader is the signal. The more rapid is the molecular motion, the larger are the values of $T_{1}$ and $T_{2}$ and the sharper are the signals ('motional narrowing'). This rule applies to small- and medium-sized molecules of the type most common in organic chemistry.
Chemical shifts and coupling constants reveal the static structure of a molecule; relaxation times reflect molecular dynamics.

## 2 RECOGNITION OF STRUCTURAL FRAGMENTS BY NMR

### 2.1 Functional groups

### 2.1.2 ${ }^{1} \mathrm{H}$ Chemical Shifts

Many functional groups can be identified conclusively by their ${ }^{I} H$ chemical shifts ${ }^{1-3}$. Important examples are listed in Table 2.1, where the ranges for the proton shifts are shown in decreasing sequence: aldehydes $\left(\delta_{H}=9.5-10.5\right)$, acetals $\left(\delta_{H}=4.5-6\right)$, alkoxy $\left(\delta_{H}=4-5.5\right)$ and methoxy functions ( $\delta_{H}=3.5-4$ ), $N$-methyl groups ( $\delta_{H}=3-3.5$ ) and methyl residues attached to double bonds such as $\mathrm{C}=\mathrm{C}$ or $\mathrm{C}=\mathrm{X}(\mathrm{X}=N, O, S)$ or to aromatic and heteroaromatic skeletons ( $\delta_{H}=1.8-$ 2.5).

Table 2.1. ${ }^{1} \mathrm{H}$ chemical shift ranges for organic compounds

Small shift values for CH or $\mathrm{CH}_{2}$ protons may indicate cyclopropane units. Proton shifts distinguish between alkyne CH (generally $\delta_{H}=2.5-3.2$ ), alkene CH (generally $\delta_{H}=4.5-6$ ) and aromatic/heteroaromatic $\mathrm{CH}\left(\delta_{H}=\sigma-9.5\right)$, and also between $\pi$-electron-rich (pyrrole, furan, thiophene, $\delta_{H}=6-7$ ) and $\pi$-electron-deficient heteroaromatic compounds (pyridine, $\delta_{H}=7.5-9.5$ ).

### 2.1.2 Deuterium exchange

Protons which arc bonded to heteroatoms (XH protons, $\mathrm{X}=O, N, S$ ) can be identified in the ${ }^{l} H$ NMR spectrum by using deuterium exchange (treatment of the sample with a small amount of $\mathrm{D}_{2} \mathrm{O}$ or $\mathrm{CD}_{3} \mathrm{OD}$ ). After the deuterium exchange:

$$
\mathrm{R}-\mathrm{XH}+\mathrm{D}_{2} \mathrm{O} \rightleftharpoons \mathrm{R}-\mathrm{XD}+\mathrm{HDO}
$$

the XH proton signals in the ${ }^{l} H$ NMR spectrum disappear. Instead, the $H$ DO signal appears at approximately $\delta_{H}=4.8$. Those protons which can be identified by $\mathrm{D}_{2} \mathrm{O}$ exchange are indicated as such in Table 2.1. As a result of $\mathrm{D}_{2} \mathrm{O}$ exchange, $X H$ protons are often not detected in the ${ }^{I} H$ NMR spectrum if this is obtaincd using a dcutcriated protic solvent (e.g. $\mathrm{CD}_{3} \mathrm{OD}$ ).

### 2.1.3 ${ }^{13} \mathrm{C}$ Chemical shifts

The ${ }^{13} \mathrm{C}$ chemical shift ranges for organic compounds ${ }^{4-6}$ in Table 2.2 show that many carboncontaining functional groups can be identified by the characteristic shift values in the ${ }^{13} \mathrm{C}$ NMR spectra.
For example, various carbonyl compounds have distinctive shifts. Ketonic carbonyl functions appear as singlets falling between $\delta_{\mathrm{C}}=190$ and 220 , with cyclopentanone showing the largest shift; although aldehyde signals between $\delta_{\mathrm{C}}=185$ and 205 overlap with the shift range of keto carbonyls, they appear in the coupled ${ }^{13} \mathrm{C}$ NMR spectrum as doublet CH signals. Quinone carbonyls occurs between $\delta_{\mathrm{C}}=180$ and 190 while the carboxy C atoms of carboxylic acids and their derivatives are generally found between $\delta_{C}=160$ and 180 . However, the ${ }^{13} \mathrm{C}$ signals of phenoxy carbon atoms, carbonates, ureas (carbonic acid derivatives), oximes and other imines also lie at about $\delta_{\mathrm{C}}=160$ so that additional information such as the empirical formula may be helpful for structure elucidation.
Other functional groups that are easily differentiated are cyanide ( $\delta_{C}=110-120$ ) from isocyanide ( $\delta_{\mathrm{C}}=135-150$ ), thiocyanate ( $\delta_{\mathrm{C}}=110-120$ ) from isothiocyanate ( $\delta_{\mathrm{C}}=125-140$ ), cyanate ( $\delta_{\mathrm{C}}=$ 105-120) from isocyanate ( $\delta_{\mathrm{C}}=120-135$ ) and aliphatic C atoms which are bonded to different heteroatoms or substituents (Table 2.2). Thus ether-methoxy generally appears between $\delta_{\mathrm{C}}=55$ and 62 , ester-methoxy at $\dot{\delta}_{\mathrm{C}}=52$; $N$-methyl generally lies between $\delta_{\mathrm{C}}=30$ and 45 and $S$-methyl at about $\delta_{C}=25$. However, methyl signals at $\delta_{C}=20$ may also arise from methyl groups attached to $\mathrm{C}=\mathrm{X}$ or $\mathrm{C}=\mathrm{C}$ double bonds, e.g. as in acctyl, $\mathrm{CH}_{3}-\mathrm{CO}-$.
If an $H$ atom in an alkane $\mathrm{R}-H$ is replaced by a substituent X , the ${ }^{13} \mathrm{C}$ chemical shift $\delta_{\mathrm{C}}$ in the $\alpha-$ position increases proportionally to the electronegativity of $\mathrm{X}(-I \mathrm{cffect})$. In the $\beta$-position, $\delta_{\mathrm{C}}$ generally also increases, whereas it decreases at the C atom $\gamma$ to the substituent ( $\gamma$-effect, see Section 2.3.4). More remote carbon atoms remain almost uninfluenced ( $\Delta \delta_{\mathrm{C}} \sim 0$ ).

R-H

In contrast to ${ }^{1} H$ shifts, ${ }^{13} \mathrm{C}$ shifts cannot in general be used to distinguish between aromatic and heteroaromatic compounds on the one hand and alkenes on the other (Table 2.2). Cyclopropane carbon atoms stand out, however, by showing particularly small shifts in both the ${ }^{13} \mathrm{C}$ and the ${ }^{1} H$ NMR spectra. By analogy with their proton resonances, the ${ }^{13} \mathrm{C}$ chemical shifts of $\pi$ electrondeficient heteroaromatics (pyridine type) are larger than those of $\pi$ electron-rich heteroaromatic rings (pyrrole type).

Table 2.2. ${ }^{13} \mathrm{C}$ chemical shift ranges for organic compounds

Substituent effects (substituent increments) tabulated in more detail in the literature ${ }^{1-6}$ demonstrate that ${ }^{13} \mathrm{C}$ chemical shifts of individual carbon nuclei in alkenes and aromatic as well as heteroaromatic compounds can be predicted approximately by means of mesomeric effects (resonance effects). Thus, an electron donor substituent $\mathrm{D}\left[\mathrm{D}=\mathrm{OCH}_{3}, \mathrm{SCH}_{3}, \mathrm{~N}\left(\mathrm{CH}_{3}\right)_{2}\right]$ attached to a $\mathrm{C}=\mathrm{C}$ double bond shields the $\beta$-C atom and the $\beta$-proton ( $+M$ effect, smaller shift), whereas the $\alpha$-position is deshielded (larger shift) as a result of substituent electronegativity ( $-I$ effect).

The reversed polarity of the double bond is induced by a $\pi$ electron-accepting substituent $\Lambda$ ( $\Lambda=$ $\mathrm{C}=\mathrm{O}, \mathrm{C}=\mathrm{N}, \mathrm{NO}_{2}$ ): the carbon and proton in the $\beta$-position are deshielded ( $-M$ effect, larger shifts). These substituents have analogous effects on the C atoms of aromatic and heteroaromatic rings. An electron donor D (see above) attached to the benzene ring deshields the (substituted) $\alpha-\mathrm{C}$ atom ( $-I$ effect). In contrast, in the ortho and para positions (or comparable positions in heteroaromatic rings) it causes a shielding ( $+M$ effect, smaller ${ }^{1} H$ and ${ }^{13} \mathrm{C}$ shifts), whereas the meta positions remain almost unaffected.

An electron-accepting substituent A (see above) induces the reverse deshielding in ortho and para positions ( $-M$ effect, larger ${ }^{l} H$ and ${ }^{13} \mathrm{C}$ shifts ), again with no significant effect on meta positions.

(-)-M-substituent (electron acceptor) bonded to the benzene ring: $\delta_{H}>7.26 ; \delta_{C}>128.5$

### 2.1.4 ${ }^{15} \mathrm{~N}$ Chemical shifts

Frequently the ${ }^{15} \mathrm{~N}$ chemical shifts ${ }^{7-9}$ (Table 2.3) of molecular fragments and functional groups containing nitrogen complement their ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ shifts. The ammonia scale ${ }^{7}$ of ${ }^{15} \mathrm{~N}$ shifts used in

Table 2.3 shows very obvious parallels with the TMS scale of ${ }^{13} \mathrm{C}$ shifts. Thus, the ${ }^{15} \mathrm{~N}$ shifts (Table 2.3) decrease in size in the sequence nitroso, nitro, imino, amino, following the corresponding behaviour of the ${ }^{13} \mathrm{C}$ shifts of carbonyl, carboxy, alkenyl and alkyl carbon atoms (Table 2.2).

Table 2.3. ${ }^{15} \mathrm{~N}$ Chemical shift ranges for organonitrogen compounds

The decrease in shifts found in ${ }^{13} \mathrm{C}$ NMR spectra in the sequence

$$
\delta_{\text {alkenes, aromatics }}>\delta_{\text {alkynes }}>\delta_{\text {alkanes }}>\delta_{\text {cyclopropanes }}
$$

also applies to the analogous N -containing functional groups, ring systems and partial structures (Tables 2.2 and 2.3):

$$
\delta_{\text {imines, pyridines }}>\delta_{\text {nitriles }}>\delta_{\text {amines }}>\delta_{\text {aziridines }}
$$

### 2.2 Skeletal structure (atom connectivities)

### 2.2.1 HH Multiplicities

The splitting (signal multiplicity) of ${ }^{l} H$ resonances often reveals the spatial proximity of the protons involved. Thus it is possible to identify structural units such as those which often occur in organic molecules simply from the appearance of multiplet systems and by using the ( $n+1$ ) rule.
The simplest example is the $A X$ or $A B$ two-spin system for all substructures containing two protons two, three or four bonds apart from each other, according to geminal, vicinal or $w$ coupling. Figure 2.1 shows the three typical examples: (a) the $A X$ system, with a large shift difference ( $v_{X}$ $-V_{A}$ ) between the coupled protons $H^{A}$ and $H^{X}$ in relation to their coupling constant $J_{A X}$; (b) the $A B$ system, with a smaller shift difference ( $v_{B}-v_{A}$ ) of the coupled nuclei ( $H^{A}$ and $H^{B}$ ) relative to their coupling constant $J_{A B}$, and (c) the $A B$ system, with a very small shift difference $\left[\left(v_{B}-v_{A}\right) \leq J_{A B}\right]$ verging on the $A_{2}$ case, whereby the outer signals are very strongly suppressed by the roofing effect ( $A B$ effect). Figure 2.2 shows the ${ }^{l} H$ NMR partial spectra of a few more structural units which can easily be identified.
Structure elucidation does not necessarily require the complete analysis of all multiplets in complicated spectra. If the coupling constants are known, the characteristic fine structure of the single multiplet almost always leads to identification of a molecular fragment and, in the case of alkenes and aromatic or heteroaromatic compounds, it may even lead to the elucidation of the complete substitution pattern.

chemically non-equivalent geminal protons (cycloalkanes, alkenes)

$C_{2}$ fragments with vicinal alkyl protons

(hetero-)aromatics with ortho- (vicinal) or meta-protons (forming a w)

Figure 2.1. $A X(A B)$ systems and typical molecular fragments

### 2.2.2 CH Multiplicities

The multiplicitics of ${ }^{13} \mathrm{C}$ signals due to ${ }^{l} J_{\mathrm{CH}}$ coupling (splitting occurs due to CH coupling across one bond) indicates the bonding mode of the C atoms, whether quaternary $\left(\mathrm{R}_{4} \mathrm{C}\right.$, singlet S$)$, tertiary ( $\mathrm{R}_{3} \mathbf{C H}$, doublet D ), secondary $\left(\mathrm{R}_{2} \mathbf{C H}_{2}\right.$, triplet T$)$ or primary ( $\mathrm{RCH}_{3}$, quartet Q ).

Figure 2.3. J-resolved two-dimensional ${ }^{13} \mathrm{C}$ NMR spectra series of $\alpha$-pinene (1) [in $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}, 25^{\circ} \mathrm{C}, 50 \mathrm{MHz}$ ]. (a) Stacked plot; (b) contour plot

Coupled ${ }^{13} \mathrm{C}$ NMR spectra which have been enhanced by NOE are suitable for analysis of CH multiplicities (gated decoupling) ${ }^{5.6}$. Where the sequence of signals in the spectra is too dense, evaluation of spin multiplicities may be hampered by overlapping. In the past this has been avoided by compression of the multiplet signals using off-resonance decoupling ${ }^{5,6}$ of the protons. More modern techniques include the $J$-modulated spin-echo technique (attached proton test, APT) ${ }^{10,11}$ and $J$-resolved two-dimensional ${ }^{13} \mathrm{C}$ NMR spectroscopy ${ }^{12,13}$, which both use $J$-modulation ${ }^{14,15}$. Figure 2.3, shows a series of $J$-resolved ${ }^{13} \mathrm{C}$ NMR spectra of $\alpha$-pinene (1) as a contour plot and as a stacked plot. The purpose of the experiment is apparent; ${ }^{13} \mathrm{C}$ shift and $J_{\mathrm{C} H}$ coupling constants are shown in two frequency dimensions so that signal overlaps occur less often.
The $J$-modulated spin-echo ${ }^{10,11}$ and the more frequently used DEPT experiment ${ }^{14,15}$ are pulse sequences, which transform the information of the CH signal multiplicity and of spin-spin coupling into phase relationships (positive and negative amplitudes) of the ${ }^{13} \mathrm{C}$ signals in the protondecoupled ${ }^{13} \mathrm{C}$ NMR spectra. The DEPT experiment benefits from a ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ polarisation transfer which increases the sensitivity by up to a factor of 4 . For this reason, this technique provides the quickest way of determining the ${ }^{13} \mathrm{C}^{l} H$ multiplicities. Figure 2.4 illustrates the application of the DEPT technique to the analysis of the CH multiplets of $\alpha$-pinene (1). Routinely the result will be the subspectrum (b) of all CH carbon atoms in addition to a further subspectrum (c), in which, besides the CH carbon atoms, the $\mathrm{CH}_{3}$ carbon atoms also show positive amplitude, whereas the $\mathrm{CH}_{2}$ carbon atoms appear as negative. Quaternary C atoms do not appear in the DEPT subspectra; accordingly, they may be identified as the signals which appear additionally in the ${ }^{\prime} H$ broadband decoupled ${ }^{13} \mathrm{C}$ NMR spectra (e.g. spectrum a in Fig. 2.4).

Figure 2.4. CH multiplicities of $\alpha$-pinene (1) [hexadeuterioacetone, $25^{\circ} \mathrm{C}, 50 \mathrm{MHz}$ ]. (a) ${ }^{1} \mathrm{H}$ broadband decoupled ${ }^{13} \mathrm{C}$ NMR spectrum; (b) DEPT subspectrum of CH ; (c) DEPT subspectrum of all C atoms which are bonded to $H$ ( CH and $\mathrm{CH}_{3}$ positive, $\mathrm{CH}_{2}$ negative); (d) an expansion of a section of (c). Signals from two quaternary C atoms, three CH units, two $\mathrm{CH}_{2}$ units and three $\mathrm{CH}_{3}$ units can be seen

Figure 2.4 illustrates the usefulness of CH multiplicities for the purpose of structure elucidation. The addition of all C, $\mathrm{CH}, \mathrm{CH}_{2}$ and $\mathrm{CH}_{3}$ units leads to a part formula $\mathrm{C}_{\mathrm{x}} \mathrm{H}_{y}$,

$$
2 \mathrm{C}+3 \mathrm{CH}+2 \mathrm{CH}_{2}+3 \mathrm{CH}_{3}=\mathrm{C}_{2}+\mathrm{C}_{3} H_{3}+\mathrm{C}_{2} H_{4}+\mathrm{C}_{3} H_{9}=\mathrm{C}_{10} H_{16}
$$

which contains all of the $H$ atoms which are bonded to C . Hence the result is the formula of the hydrocarbon part of the molecule, e.g. that of $\alpha$-pinene (1, Fig. 2.4).
If the $\mathrm{C} H$ balance given by the $\mathrm{C} H$ multiplicities differs from the number of $H$ atoms in the molecular formula, then the additional $H$ atoms are bonded to heteroatoms. The ${ }^{13} \mathrm{C}$ NMR spectra in Fig. 2.5 show, for example, for isopinocampheol (2), $\mathrm{C}_{10} \mathrm{H}_{18} \mathrm{O}$, a quaternary C atom (C), four CH units $\left(\mathrm{C}_{4} H_{4}\right)$, two $\mathrm{CH}_{2}$ units $\left(\mathrm{C}_{2} H_{4}\right)$ and three $\mathrm{CH}_{3}$ groups $\left(\mathrm{C}_{3} H_{9}\right)$. In the CH balance, $\mathrm{C}_{10} H_{17}$, one $H$ is missing when compared with the molecular formula, $\mathrm{C}_{10} H_{18} \mathrm{O}$; to conclude, the compound contains one OH group.

Figure 2.5. CH multiplicities of isopinocampheol (2), $\mathrm{C}_{10} \mathrm{H}_{18} \mathrm{O}\left[\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}, 25^{\circ} \mathrm{C}, 50 \mathrm{MHz}\right]$. (a) ${ }^{1} \mathrm{H}$ broadband decoupled ${ }^{13} \mathrm{C}$ NMR spectrum; (b) DEPT CH subspectrum; (c) DEPT subspectrum of all $C$ atoms which are bonded to $\mathrm{H}\left(\mathrm{CH}\right.$ and $\mathrm{CH}_{3}$ positive, $\mathrm{CH}_{2}$ negative)

### 2.2.3 HH Coupling constants

Since spin-spin coupling ${ }^{2,3}$ through bonds occurs because of the interaction between the magnetic moments of the atomic nuclei and the bonding electrons, the coupling constants ${ }^{2,3}$ reflect the bonding environments of the coupled nucei. In ${ }^{1} H$ NMR spectroscopy geminal coupling through two bonds $\left({ }^{2} J_{H H}\right)$ and vicinal coupling through three bonds $\left({ }^{3} J_{H H}\right)$ provide insight into the nature of these bonds.

Table 2.4. Typical $H H$ coupling constants $(H z)$ of some units in alicycles, alkenes and alkynes ${ }^{2,3}$

Geminal $H H$ coupling, ${ }^{2} J_{H H}$, depends characteristically on the polarity and hybridisation of the C atom on the coupling path and also on the substituents and on the $H \mathrm{CH}$ bond angle. Thus ${ }^{2} J_{H H}$ coupling can be used to differentiate between a cyclohexane ( 12.5 Hz ), a cyclopropanc ( 4.5 Hz ) or an alkene ( 2.5 Hz ), and to show whether electronegative heteroatoms are bonded to methylene groups (Table 2.4). In cyclohexane and norbornane derivatives the $w$-shaped arrangement of the bonds between protons attached to alternate C atoms leads to distinctive ${ }^{4} J_{H H}$ coupling ( $w$-couplings, Table 2.4).
Vicinal $H H$ coupling constants, ${ }^{3} J_{H H}$, are especially useful in determining the relative configuration (see Section 2.3.1). However, they also reflect a number of other distinguishing characteristics, e.g. the ring size for cycloaikenes (a low value for small rings) and the $\alpha$-position of electronegative heteroatoms in heterocycles which is reflected by remarkably small coupling constants ${ }^{3} J_{H H}$ (Table 2.5).
The coupling constants of ortho ( ${ }^{3} J_{H H}=7 \mathrm{~Hz}$ ), meta $\left({ }^{4} J_{H H}=1.5 \mathrm{~Hz}\right)$ and para protons ( ${ }^{5} J_{H H} \leq 1$ Hz ) in benzene and naphthalene ring systems are especially useful in structure elucidation (Table 2.5 ). With naphthalene and other condensed (hetero-) aromatics, a knowledge of 'zig zag' coupling $\left({ }^{5} J_{H H}=0.8 \mathrm{~Hz}\right)$ is helpful in deducing substitution patterns.

Table 2.5. Typical $H H$ coupling constants $(H z)$ of aromatic and heteroaromatic compounds ${ }^{2,3}$
coses)

The $H H$ coupling constants of pyridine (Table 2.5) reflect the positions of the coupling protons relative to the nitrogen ring. There is a particularly clear difference here between the protons in the 2- and 3-positions ( ${ }^{3} J_{H H}=5.5 \mathrm{~Hz}$ ) and those in the 3- and 4-positions ( ${ }^{3} J_{H H}-7.6 \mathrm{~Hz}$ ). Similarly, HH coupling constants in five-membered heteroaromatic rings such as thiophene, pyrrole and furan can be distinguished because of the characteristic effects of the electronegative heteroatoms on their ${ }^{3} J_{H H}$ couplings (Table 2.5); in particular the ${ }^{3} J_{H H}$ coupling of the protons in the 2 - and 3positions, allow the heteroatoms to be identified (the more electronegative the heteroatom, the smaller is the value of ${ }^{3} J_{H H}$ ).
In the case of alkenes and aromatic and heteroaromatic compounds, analysis of a single multiplet will often clarify the complete substitution pattern. A few examples will illustrate the procedure.
If, for example, four signals are found in regions appropriate for benzene ring protons ( $\delta_{H}=6-9$, four protons on the basis of the height of the integrals), then the sample may be a disubstituted benzene (Fig. 2.6). The most effective approach is to analyse a multiplet with a clear fine structure
and as many coupling constants as possible, e.g. consider the threefold doublet at $\delta_{H}=7.5$ (Fig. 2.6 a); it shows two ortho couplings ( 8.0 and 7.0 Hz ) and one meta coupling ( 2.5 Hz ); hence relative to the $H$ atom with a shift value of $\delta_{H}=7.5$, there are two protons in ortho positions and one in a meta position; to conclude, the molecule is an ortho-disubstituted benzene ( $o$-nitrophenol, $\mathbf{3}$ ).

Figure 2.6. ${ }^{1} \mathrm{H} \mathrm{NMR}$ spectra of disubstituted benzene rings $\left[\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 200 \mathrm{MHz}\right]$. (a) o-Nitrophenol (3); (b) $m$-nitrobenzaldehyde (4); (c) 4,4'-dimethoxybenzil (5)

A meta disubstituted benzene (Fig. 2.6 b) shows only two ortho couplings ( ${ }^{3} J_{H H}=7.5 \mathrm{~Hz}$ ) for one signal ( $\delta_{H}=7.8$ ) whereas another signal $\left(\delta_{H}=8.74\right)$ exhibits only two meta couplings $\left({ }^{4} J_{H H}=3.0\right.$ and 2.5 Hz ). In both cases one observes either a triplet $\left(\delta_{H}=7.8\right)$ or a doublet of doublets ( $\delta_{H}=$ 8.74) depending on whether the couplings $\left({ }^{3} J_{H H}\right.$ or $\left.{ }^{4} J_{H H}\right)$ are equal or different.

The $A A^{\prime} X X^{\prime}$ systems (Section 1.5 ) ${ }^{2,3}$ which are normally easily recognisable from their symmetry identify para-disubstituted benzenes such as 4,4'-dimethoxybenzil (5) or 4- substituted pyridines.
This method of focusing on a ${ }^{l} \mathrm{H}$ multiplet of clear fine structure and revealing as many HH coupling constants as possible affords the substitution pattern for an alkene or an aromatic or a heteroaromatic compound quickly and conclusively. One further principle normally indicates the geminal, vicinal and $w$ relationships of the protons of a molecule, the so called $H H$ connectivities, i.e. that coupled nuclei have identical coupling constants. Accordingly, once the coupling constants of a multiplet have all been established, the appearance of one of these couplings in another multiplet identifies (and assigns) the coupling partner. This procedure, which also leads to the solutions to problems 1-12, may be illustrated by means of two typical examples.

Figure 2.7. ${ }^{1} \mathrm{H}$ NMR spectrum of 3,4-dimethoxybenzaldehyde (6) [aromatic shift range, $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}$, (a) 100 MHz , (b) 200 MHz ]

In Fig. 2.7 the ${ }^{I} H$ signal with a typical aromatic proton shift of $\delta_{H}=7.1$ shows a doublet of doublets with $J$-values of 8.5 Hz (ortho coupling, ${ }^{3} J_{H H}$ ) and 2.5 Hz (meta coupling, ${ }^{4} J_{H H}$ ). The ring proton in question therefore has two protons as coupling partners, one in the ortho position (8.5

Hz ) and another in the meta position ( 2.5 Hz ), and moreover these are in such an arrangement as to make a second ortho coupling impossible. Thus the benzene ring is $1,2,4-$ trisubstituted (6). The ring protons form an $A M X$ system, and, in order to compare the change of frequency dispersion and 'roofing' effects with increasing magnetic field strength, this is shown first at 100 MHz and then also at 200 MHz . The para coupling ${ }^{5} J_{A X^{\prime}}$ which is less frequently visible, is also resolved. From the splitting of the signal at $\delta_{H}=7.1\left(H^{M}\right)$ a 1,2,3-trisubstituted benzene ring (7) might have been considered. In this case, however, the ortho proton $\left(H^{A}\right)$ would have shown a second ortho coupling to the third proton $\left(H^{X}\right)$.
The application of the principle that coupled nuclei will have the same coupling constant enables the ${ }^{1} H$ NMR spectrum to be assigned completely (Fig. 2.7). The ortho coupling, ${ }^{3} J_{A M}=8.5 \mathrm{~Hz}$, is repeated at $\delta_{H}=6.93$ and allows the assignment of $H^{A}$; the meta coupling, ${ }^{4} J_{M X}=2.5 \mathrm{~Hz}$, which appears again at $\delta_{H}=7.28$, gives the assignment of $H^{\mathrm{x}}$.
The four signals in the ${ }^{1} H$ NMR spectrum of a pyridine derivative (Fig. 2.8) show first that it is a 2- or 3-monosubstituted derivative; a 4-monosubstituted pyridine would display an $A A^{\prime} X X^{\prime}$ system. The signal with the smallest shift $\left(\delta_{H}=7.16\right)$ splits into a threefold doublet with coupling constants $8.1,4.8$ and 0.7 Hz . The two $J_{H H}$ couplings of 8.1 and 4.8 Hz unequivocally belong to a $\beta$ proton of the pyridine ring according to Table 2.5 . Step by step assignment of all three couplings (Fig. 2.8) leads to a pyridine ring 8 substituted in the 3-position. Again, signals are assigned following the principle that coupled nuclei will have the same coupling constant; the coupling constants identified from Table 2.5 for the proton at $\delta_{H}=7.16$ are then sought in the other multiplets.

### 2.2.4 CH Coupling constants

One-bond CH coupling constants $J_{C H}\left({ }^{l} J_{\mathrm{CH}}\right)$ are proportional to the $s$ character of the hybrid bonding orbitals of the coupling carbon atom, (Table 2.6 , from left to right) ${ }^{4-6,16}$, according to

$$
\begin{equation*}
J_{C H}=500 \mathrm{~s} \tag{1}
\end{equation*}
$$

where $s=0.25,0.33$ and 0.5 for $\mathrm{sp}^{3}-\mathrm{sp}^{2}$ - and sp-hybridised C atoms, respectively.
With the help of these facts, it is possible to distinguish between alkyl-C ( $J_{\mathrm{CH}} \sim 125 \mathrm{~Hz}$ ), alkenyland aryl-C ( $J_{\mathrm{CH}} \sim 165 \mathrm{~Hz}$ ) and alkynyl-C ( $J_{\mathrm{CH}} \sim 250 \mathrm{~Hz}$ ), e.g. as in problem 15.
It is also useful for structure elucidation that $J_{C H}$ increases with the electronegativity of the heteroatom or substituent bound to the coupled carbon atom (Table 2.6, from top to bottom).

Table 2.6. Structural features (carbon hybridisation, electronegativity, ring size) and typical one-bond CH coupling constants $J_{\mathrm{CH}}(\mathrm{Hz})^{4-6,16}$
Chybridisation

From typical vaiues for $J_{C H}$ coupling, Tabie 2.6 shows:
In the chemical shift range for aliphatic compounds
cyclopropane rings (ca 160 Hz reflect large $s$ character of bonding hybrid orbitals);
oxirane (epoxide) rings (ca 175 Hz additionally reflect electronegativity of ring oxygen atom);
cyclobutane rings (ca 135 Hz );
O-alkyl groups ( $145-150 \mathrm{~Hz}$ );
$N$-alkyl groups ( 140 Hz );
acetal-C atoms (ca 170 Hz at $\delta_{\mathrm{C}}=100$ );
terminal ethynyl groups ( $c a 250 \mathrm{~Hz}$ ).

In the chemical shift range for alkenes and aromatic and heteroaromatic compounds
enol ether fragments (furan, pyrone, isoflavone, $195-200 \mathrm{~Hz}$ );
2-unsubstituted pyridine and pyrrole ( $c a 180 \mathrm{~Hz}$ );
2-unsubstituted imidazole and pyrimidine ( $>200 \mathrm{~Hz}$ ).
Geminal CH coupling ${ }^{2} J_{\mathrm{CH}}$ becomes more positive with increasing CCH bond angle and with decreasing electronegativity of the substituent on the coupling C . This property enables a distinction to be made inter alia between the substituents on the benzene ring or between heteroatoms in five-ring heteroaromatics (Table 2.7). From Table 2.7, those ${ }^{2} J_{C H}$ couplings which may be especially clearly distinguished and diagnostic are:
$\beta$-C atoms in imines (e.g. C-3 in pyridine: 7 Hz );
$\alpha$-C atoms in aldehydes ( 25 Hz );
substituted (non-protonated) C atoms of terminal ethynyl groups $(40-50 \mathrm{~Hz})$.

Table 2.7. Structural features and geminal (two-bond) CH coupling constants ${ }^{2} J_{\mathrm{CH}}(\mathrm{Hz}){ }^{4-6,16}$

Vicinal CH couplings ${ }^{3} J_{\mathrm{CH}}$ depend not only on the configuration of the coupling C and $H$ (Table 2.8; see Section 2.3.2), but also on the nature and position of substituents: an electronegative substituent raises the ${ }^{3} J_{\mathrm{CH}}$ coupling constant on the coupled C and lowers it on the coupling path, e.g. in alkenes and bonzone rings (Tablc 2.8). An imino- $N$ on the coupling path (e.g. from C-2 to $6-H$ in pyridine, Table 2.8 ) is distinguished by a particularly large ${ }^{3} J_{\mathrm{CH}}$ coupling constant ( 12 Hz ). In the ${ }^{13} \mathrm{C}$ NMR spectra of benzene derivatives, apart from the ${ }^{l} J_{\mathrm{C} H}$, only the meta coupling $\left({ }^{3} J_{\mathrm{C} H}\right.$, but not ${ }^{2} J_{\mathrm{C} H}$ ) is usually resolved. A benzenoid CH, from whose perspective the meta positions are substituted, usually appears as a ${ }^{l} J_{\mathrm{CH}}$ doublet without additional splitting, e.g. in the case of 3,4-dimethoxy- $\beta$-methyl- $\beta$-nitrostyrene (9, Fig. 2.9) the carbon atom C-5 generates a doublet at $\delta_{\mathrm{C}}=$ 111.5 in contrast to $\mathrm{C}-2$ at $\delta_{\mathrm{C}}=113.5$ which additionally splits into a triplet. The use of CH coupling constants as criteria for assigning a resonance to a specific position is illustrated by this example.

Figure 2.9. ${ }^{13} \mathrm{C}$ NMR spectra of 3,4-dimethoxy- $\beta$-methyl- $\beta$-nitrostyrene (9) $\left[\mathrm{CDCl}_{3}, 25{ }^{\circ} \mathrm{C}, 20 \mathrm{MHz}\right.$ ]. (a, b) ${ }^{1} \mathrm{H}$ broadband decoupled, (a) complete spectrum with $\mathrm{CH}_{3}$ quartets at $\delta_{\mathrm{C}}=14.1$ and 56.0 ; ( $\mathbf{b}, \mathbf{c}$ ) decoupled and coupled partial spectrum of benzenoid and alkene carbon atoms, (c) obtained by 'gated' decoupling

${ }^{\text {a }}$ The quotation marks indicate that the coupling constants are virtually the same for non-equivalent protons. $\mathrm{C}-\beta$ should, for example, split into a doublet ( ${ }^{2} \mathrm{~J}_{\mathrm{CH}}$ to $\left.\alpha-\mathrm{H}\right)$ of quartets $\left({ }^{2} \mathrm{~J}_{\mathrm{CH}}\right.$ to $\beta-\mathrm{CH}_{3}$; since both couplings have the same value ( 7.5 Hz ), a pseudoquintet 'qui' is observed

Table 2.8. Structural features and vicinal (three-bond) CH coupling constants ${ }^{3} \mathrm{~J}_{\mathrm{CH}}(\mathrm{Hz})^{46,16}$
Relative configuration

Usually there is no splitting between two exchangeable XH protons ( $\mathrm{X}=O, N, S$ ) and C atoms through two or three bonds $\left({ }^{2} J_{\mathrm{CH}}\right.$ or $\left.{ }^{3} J_{\mathrm{C} H}\right)$, unless solvation or an intramolecular $H$ bridge fix the $X H$ proton in the molecule. Thus the C atoms ortho to the hydroxy group show ${ }^{3} J_{\mathrm{C} H}$ coupling to the hydrogen bonding OH proton in salicylaldehyde (10), whose values reflect the relative configurations of the coupling partners. This method may be used, for example, to identify and assign the resonances in problem 17.

### 2.2.5 NH Coupling constants

Compared with ${ }^{I} \mathrm{H}$ and ${ }^{13} \mathrm{C}$, the magnetic moment of ${ }^{15} \mathrm{~N}$ is very small and has a negative value. The N $H$ coupling constants are correspondingly smaller and their signs are usually the reverse of comparable $H H$ and CH couplings ${ }^{7-9}$. Table 2.9 shows that the one-bond $\mathrm{N} H$ coupling, $J_{N H}$, is proportional to the $s$-character of the hybrid bonding orbital on $N$ so a distinction can be made ${ }^{15}$ between amino- and imino-NH. Formamides can be identificd by large ${ }^{2} J_{N H}$ couplings between ${ }^{15} \mathrm{~N}$ and the formyl proton. The ${ }^{2} J_{N H}$ and ${ }^{3} J_{N H}$ couplings of pyrrole and pyridine are especially distinctive and reflect the orientation of the non-bonding electron pair on nitrogen (pyrrole: perpendicular to the ring plane; pyridine: in the ring plane; Table 2.9), a fact which can be exploited in the identification of heterocyclic compounds (problems 30 and 31).

Table 2.9. Structural features and typical NH coupling constants $(\mathrm{Hz})^{7}$

### 2.2.6 $\mathrm{HH} \operatorname{COSY}$ (geminal, vicinal, w-relationships of protons)

The $H H$ COSY experiment ${ }^{12-13,17-19}$ in proton magnetic resonance is a quick alternative to spin decoupling ${ }^{2,3}$ in structure elucidation. 'COSY' is the acronym derived from correlation spectroscopy. $H H$ COSY correlates the ${ }^{l} H$ shifts of the coupling protons of a molecule. The proton shifts are plotted on both frequency axes in the two-dimensional experiment. The result is a diagram with square symmetry (Fig. 2.10). The projection of the one-dimensional ${ }^{l} H$ NMR spectrum appears on the diagonal (diagonal signals). In addition there are correlation or cross signals (offdiagonal signals) where the protons arc coupled with one another. Thus the HH COSY diagram indicates $H H$ connectivities, that is, geminal, vicinal and $w$-relationships of the $H$ atoms of a molecule and the associated structural units.
An $H H$ COSY diagram can be shown in perspective as a stacked plot (Fig. 2.10a). Interpretation of this neat, three-dimensional representation, where the signal intensity gives the third dimension, can prove difficult because of distortions in the perspective. The contour plot can be interpreted more easily. This shows the signal intensity at various cross-sections (contour plots, Fig. 2.10b). However the choice of the plane of the cross-section affects the information provided by an HH COSY diagram; if the plane of the cross-section is too high then the cross signals which are weak are lost; if it is too low, then wcaker artcfacts may be mistaken for cross signals.
Every $H H$ coupling interaction can be identified in the $H H$ COSY contour plot by two diagonal signals and the two cross signals of the coupling partners, which form the four corners of a square. The coupling partner (cross signal) of a particular proton generates a signal on the vertical or horizontal line from the relevant ${ }^{1} \mathrm{H}$ signal. In Fig. $2.10 \mathbf{b}$, for example, the protons at $\delta_{H}=7.90$ and 7.16 are found as coupling partners on both the vertical and the horizontal lines from the proton 2 $H$ of quinoline (11) at $\delta_{H}=8.76$. Since $2-H\left(\delta_{H}=8.76\right)$ and $3-H\left(\delta_{H}=7.16\right)$ of the pyridine ring in 11 can be identified by the common coupling ${ }^{3} J_{H H}=5.5 \mathrm{~Hz}$ (Table 2.5), the $H H$ relationship which is likewise derived from the $H H$ COSY diagram confirms the location of the pyridine protons in 11a. Proton $4-H$ of quinoline ( $\delta_{H}=7.90$ ) shows an additional cross signal at $\delta_{H}=8.03$ (Fig. 2.10). If it is known that this so-called zig-zag coupling is attributable to the benzene ring proton $8-H$
(11b), then two further cross signals from $\delta_{H}=8.03$ (at $\delta_{H}=7.55$ and 7.35) locate the remaining protons of quinoline (11c).

Figure 2.10. $\mathrm{HH} \operatorname{COSY}$ diagram of quinoline (11) $\left[\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}, 95 \% \mathrm{v} / \mathrm{v}, 25^{\circ} \mathrm{C}, 400 \mathrm{MHz}, 8\right.$ scans, 256 experiments]. (a) Stacked plot; (b) contour plot

Figure 2.11. Proton-Proton shift correlations of $\alpha$-pinene (1) [purity $99 \%, \mathrm{CDCl}_{3}, 5 \% \mathrm{v} / \mathrm{v}, 25^{\circ} \mathrm{C}, 500 \mathrm{MHz}, 8$ scans, 256 experiments]. (a) HH COSY; (b) HH TOCSY; (c) selective one-dimensional HH TOCSY, soft pulse irradiation at $\delta_{H}=5.20$ (signal not shown), compared with the ${ }^{1} H$ NMR spectrum on top; deviations of chemical shifts from those in other experiments (Fig. 2.14, 2.16) arise from solvent effects

This example (Fig. 2.10) also shows the limitations of the $H H$ COSY experiment: first, evaluation, without taking known shifts and possible couplings into account, is not always conclusive because the cross-sectional area of the cross signals may not reveal which specific couplings are involved; second, overlapping signals (e.g. $\delta_{H}=7.55$ and 7.60 in Fig. 2.10) are not separated by $H H$ COSY if the relevant protons couple to one another. If there is sufficient resolution, however, the fine structure of the multiplets may be recognised by the shapes of the diagonal and cross signals, e.g. in Fig. 2.10, at $\delta_{H}=7.55$ there is a triplet, therefore the resonance at $\delta_{H}=7.60$ is a doublet (see the shape of the signal on the diagonal at $\delta_{H}=7.55-7.60$ in Fig. 2.10).
In the case of $(m+1)$ - and ( $n+1$ )-fold splittings of $A_{m} X_{n}$ systems in one-dimensional ${ }^{l} H$ NMR spectra the $H H$ COSY plot gives, depending on the resolution, up to $(m+1)(n+1)$-fold splittings of the cross signals. If several small coupling constants contribute to a multiplet, the intensity of the cross signals in the $H H$ COSY may be distributed into many multiplet signals so that even at a low-lying cross-section no cross signals appear in the contour diagram. Despite these limitations, structural fragments may almost always be derived by means of the $H H$ COSY, so that with complementary information from other NMR experiments it is possible to deduce the complete structure. Thus the $H H$ COSY is especially useful for solving the problems $12,32,33,38,46$ and 52.
Modifications of the basic $H H \operatorname{COSY}{ }^{17}$ include "COSY $45^{\prime \prime}$ with an initial $45^{\circ}$ pulse to suppress diagonal signals for a better separation of cross signals near the diagonal or "COSY with delay" to emphasise connectivities which are the result of smaller couplings. The "TOCSY" experiment (from total correlation spectroscopy) ${ }^{2}$ detects cross signals of an individual proton with all other protons coupled to each other within a larger structural unit, e.g. a ring, the range depending on the adjustable time of isotropic magnetisation transfer. Thus, the endo-methylene proton of $\alpha$-pinene at $\delta_{H}=1.16$ displays only one cross signal with the exo-methylene proton ( $\delta_{H}=2.34$ ) due to geminal coupling in the $H H$ COSY experiment (Fig. 2.11a), whereas additional cross signals with $\delta_{H}=1.94,2.07,2.17$ and 2.21 appear in the $H H$ TOCSY plot (Fig. 2.11b), thus revealing a considerably larger partial structure. One-dimensional $H H$ TOCSY experiments involve irradiation with a selective ("soft") pulse adjustable to any non-overlapping proton signal of the molecule. Fig. 2.11 $\mathbf{c}$, for example, detects all protons of the cyclohexene substructure including the methylene group in a one-dimensional $H H$ TOCSY with selective irradiation of the alkene proton $\left(\delta_{H}=5.20\right)$.

### 2.2.7 CC INADEQUATE (CC bonds)

Once all of the CC bonds in a molecule are known, then its carbon skeleton is established. One way to identify the CC bonds would be to measure ${ }^{13} \mathrm{C}-{ }^{13} \mathrm{C}$ coupling constants, since these are the same for C atoms which are bonded to one another: identical coupling constants are known to identify the coupling partners (see Section 2.2.3). Unfortunately, this method is complicated by two factors: first, ${ }^{13} \mathrm{C}-{ }^{13} \mathrm{C}$ couplings, especially those in the aliphatic region, are nearly all the same ( $J_{\mathrm{CC}}=35-40 \mathrm{~Hz}{ }^{16}$, Fig. 2.12), provided that none of the coupling C atoms carries an electronegative substituent. Second, the occurrence of ${ }^{13} \mathrm{C}_{-}{ }^{13} \mathrm{C}$ coupling requires the two nuclei to be directly bonded. However, given the low natural abundance of ${ }^{13} \mathrm{C}\left(1.1 \%\right.$ or $\left.10^{-2}\right)$, the probability of a ${ }^{13} \mathrm{C}^{13} \mathrm{C}$ bond is only $10^{-4}$. Splitting as a result of ${ }^{13} \mathrm{C}-{ }^{13} \mathrm{C}$ coupling therefore appears only as a weak feature in the spectrum ( $0.5 \%$ intensity), usually in satellites which are concealed by noise at a distance of half the ${ }^{13} \mathrm{C}^{13} \mathrm{C}$ coupling constant on either side of the ${ }^{13} \mathrm{C}^{-12} \mathrm{C}$ main signal $(99 \%$ intensity).
The one-dimensional variations of the INADEQUATE experiment ${ }^{12,13,17,20}$ suppress the intense ${ }^{13} \mathrm{C}-{ }^{12} \mathrm{C}$ main signal, so that both $A X$ and $A B$ systems appear for all ${ }^{13} \mathrm{C}-{ }^{13} \mathrm{C}$ bonds in one spectrum. The two-dimensional methods ${ }^{12,13,17,21,22}$ segregate these $A B$ systems on the basis of their indivi-
dual double quantum frequencies (the sum of the ${ }^{13} \mathrm{C}$ shifts of $A$ and $B$ ) as a second dimension. Using the simple example of 1-butanol (12), Fig. 2.12a demonstrates the use of the twodimensional INADEQUATE experiment for the purpose of structure elucidation. For every C-C bond the contour diagram gives an $A B$ system parallel to the abscissa with double quantum frequency as ordinate. By following the arrows in Fig. 2.12a, the carbon-carbon bonds of 1-butanol can be derived immediately. The individual $A B$ systems may also be plotted one-dimensionally (Fig. 2.12b); the ${ }^{13} \mathrm{C}^{-13} \mathrm{C}$ coupling constants often provide useful additional information.

Figure 2.12. Two-dimensional (2D-)NADEQUATE diagram of 1 -butanol (12) [( $\left.\mathrm{CD}_{3}\right)_{2} \mathrm{CO}, 95 \% \mathrm{v} / \mathrm{v}, 25^{\circ} \mathrm{C}, 50$ $\mathrm{MHz}, 128$ scans, 128 experiments]. (a) Contour plot with the $A B$ systems of bonded $C$ atoms on the horizontal axis; (b) plots of the three $A B$ systems of the molecule obtained from (a); (c) contour plot of the symmetrised INADEQUATE experiment showing the $A B$ or $A X$ systems of bonded $C$ atoms in the $H H$ COSY format (cross signals on the axes perpendicular to the diagonal)

A variation on the INADEQUATE technique, referred to as symmetrised 2D INADEQUATE ${ }^{17,21,22}$, provides a representation in the $H H$ COSY format with its quadratic symmetry of the diagonal and cross signals. Here the one-dimensional ${ }^{l} H$ broadband decoupled ${ }^{13} \mathrm{C}$ NMR spectrum is projected on to the diagonal and the $A B$ systems of all C - C bonds of the molecule are projected on to individual orthogonals (Fig. 2.12c). Every $\mathrm{C}-\mathrm{C}$ bond then gives a square defined by diagonal signals and off-diagonal $A B$ patterns, and it is possible to evaluate as described for $H H$ COSY.
A disadvantage is the naturally low sensitivity of the INADEQUATE technique. However, if one has enough substance (more than 5 mg per C atom, samples from syntheses), then the sophistica-
ted experiment is justified as the solutions to the problems $21,22,35,36$ and 37 illustrate. Fig.2.13 is intended to demonstrate the potential of this technique for tracing out a bicyclic carbon skeleton using the example of isopinocampheol (2). The evaluation of all CC- $A B$ systems on the orthogonals leads to the eleven $\mathrm{C}-\mathrm{C}$ bonds $\mathrm{a}-\mathrm{k}$. If all the $\mathrm{C}-\mathrm{C}$ bonds which have been found are combined, then the result is the bicyclic system ( $\mathrm{a}-\mathrm{h}$ ) and the three methyl substituents ( $\mathrm{i}-\mathrm{k}$ ) of the molecule $\mathbf{2}$.

b

Figure 2.13. Symmetrised two-dimensional INADEQUATE experiment with isopinocampheol (2) [(CD $\left.{ }_{3}\right)_{2} \mathrm{CO}, 250$ mg in $0.3 \mathrm{ml}, 25^{\circ} \mathrm{C}, 50 \mathrm{MHz}, 256$ scans and exp.]. (a) Stacked plot of the section between $\delta_{\mathrm{C}}=20.9$ and 48.2 ; (b) complete contour plot with cross signal pairs labelled a-k for the 11 CC bonds of the molecule to facilitate the assignments sketched in formula 2

The point of attachment of the OH group within the molecule (at $\delta_{\mathrm{C}}=70.7$ ) is revealed by the DEPT technique in Fig. 2.5. Figure 2.13 also shows the $A B$ effect on the ${ }^{13} \mathrm{C}$ signals of neighbouring $C$ atoms with a small shift difference (bond $g$ with $\delta_{C}=47.4$ and 48.2): the intense inner signals appear very clearly; the weak outer signals of the $A B$ system of these two C atoms are barely recognisable except as dots. Additional cross signals without resolved doublet structure, e.g. between $\delta_{C}=48.2$ and 42.1 , are the result of smaller ${ }^{2} J_{C C}$ and ${ }^{3} J_{C C}$ couplings.

### 2.2.8 Two-dimensional carbon-proton shift correlation via one-bond CH coupling

The CH COSY technique ${ }^{12,13,17,23}$ with carbon-13 detection and proton decoupling, and more sensitive and thus time saving methods with ${ }^{l} H$ detection and ${ }^{13} \mathrm{C}$ decoupling denoted as inverse CH COSY, correlate ${ }^{13} \mathrm{C}$ shifts in one dimension with the ${ }^{1} \mathrm{H}$ shifts in the other via one-bond CH coupling $J_{C H}$.
The pulse sequence which is used to record CH COSY involves the ${ }^{l} \mathrm{H}_{-}{ }^{13} \mathrm{C}$ polarisation transfer which is the basis of the DEPT sequence and which increases the sensitivity by a factor of up to four. Consequently, a CH COSY experiment does not require any more sample than a ${ }^{l} H$ broadband decoupled ${ }^{13} \mathrm{C}$ NMR spectrum. The result is a two-dimensional CH correlation, in which the ${ }^{13} \mathrm{C}$ shift is mapped on to the abscissa and the ${ }^{1} H$ shift is mapped on to the ordinate (or vice versa). The ${ }^{13} \mathrm{C}$ and ${ }^{l} H$ shifts of the ${ }^{l} H$ and ${ }^{13} \mathrm{C}$ nuclei which are bonded to one another are read as coordinates of the cross signal as shown in the CH COSY stacked plot (Fig. 2.14b) and the associated contour plots of the $\alpha$-pinene (Fig. 2.14a and $\mathbf{c}$ ). To evaluate them, one need only read off the coordinates of the correlation signals. In Fig. 2.14c, for example, the protons with shifts $\delta_{H}=1.16$ (proton $A$ ) and 2.34 (proton $B$ of an $A B$ system) are bonded to the C atom at $\delta_{\mathrm{C}}=31.5$. Formula 1 shows all of the CH connectivities ( CH bonds) of $\alpha$-pinene which can be read from Fig. 2.14.
$H C$ HMQC (heteronuclear multiple quantum coherence) and HC HSQC (heteronuclear single quantum coherence) are the acronyms of the pulse sequences used for inverse carbon-proton shift correlations. These sensitive inverse experiments detect one-bond carbon-proton connectivities within some minutes instead of some hours as required for CH COSY as demonstrated by an $H \mathrm{C}$ HSQC experiment with $\alpha$-ninene in Fig. 2.15.
Carbon-proton shift correlations are particularly attractive for structure elucidation because they allow the shifts of two nuclei $\left({ }^{1} H\right.$ and $\left.{ }^{13} \mathrm{C}\right)$ to be measured in a single experiment and within a feasible time scale. They determine all CH bonds (the CH connectivities) of the molecule, and hence provide an answer to the problem as to which ${ }^{1} H$ nuclei are bonded to which ${ }^{13} \mathrm{C}$ nuclei. The ${ }^{i} H$ multiplets, which so trequently overlap in the ${ }^{i} H$ domain, are almost always separated in the second dimension because of the larger frequency dispersion of the ${ }^{13} \mathrm{C}$ shifts. This proves to be particularly advantageous especially in the case of larger molecules, a feature illusirated by the identification of several natural products (problems 43-55). The resolution of overlapping $A B$ systems as in the case of ring $\mathrm{CH}_{2}$ groups in steroids and in di- and triterpenes is especially helpful (problem 51). If there is sufficiently good resolution of the proton dimension in the spectrum, it may even be possible to recognise the fine structure of the ${ }^{1} H$ multiplets from the shape of the correlation signals, a feature which is useful for solving problems 32,48 and 51.

Figure 2.14 (page 37). CH COSY diagram of $\alpha$-pinene $\left[\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}, 10 \% \mathrm{v} / \mathrm{V}, 25^{\circ} \mathrm{C}, 50 \mathrm{MHz}\right.$ for ${ }^{13} \mathrm{C}, 200 \mathrm{MHz}$ for ${ }^{1} \mathrm{H}, 64$ scans, 256 experiments]. (a) Complete contour plot; (b) stacked plot of the signals for the section outlined in (a) from $\delta_{\mathrm{C}}=20.9$ to $47.2\left({ }^{13} \mathrm{C}\right.$ ) and $\delta_{H}=0.85$ to $2.34\left({ }^{1} \mathrm{H}\right)$; (c) contour plot of section (b), showing onedimensional ${ }^{13} \mathrm{C}$ and ${ }^{1} \mathrm{H}$ NMR specta for this section aligned parallel to the abscissa and the ordinate

Figure 2.15. HC HSQC experiment (contour plot) of $\alpha$-pinene $\left[\left(\mathrm{CDCl}_{3}, 5 \% \mathrm{v} / \mathrm{v}, 25^{\circ} \mathrm{C}, 125 \mathrm{MHz}\right.\right.$ for ${ }^{13} \mathrm{C}, 500$ MHz for ${ }^{1} \mathrm{H}, 4$ scans, 256 experiments]. This experiment gives the same information as Fig. 2.14 within 8 minutes instead of two hours required for the CH -COSY in Fig. 2.14 due to higher sensitivity because of proton detection and stronger magnetic field. Deviations of proton shifts from those in Fig. 2.14 arise from the change of the solvent. The methylene protons collapsing in Fig. 2.14 at $\delta_{H}=2.19(200 \mathrm{MHz})$ display in this experiment an $A B$ system with $\delta_{A}=2.17$ and $\delta_{B}=2.21(500 \mathrm{MHz})$

### 2.2.9 Two-dimensional carbon-proton shift correlation via long-range CH coupling

Two-dimensional CH correlations such as CH COSY or HC HMQC and HSQC provide the ${ }^{1} J_{C H}$ connectivities, and thereby apply only to those C atoms which are linked to $H$ and not to nonprotonated C atoms. Modifications of these techniques, also applicable to quaternary C atoms, are those which are adjusted to the smaller ${ }^{2} J_{\mathrm{CH}}$ and ${ }^{3} J_{\mathrm{CH}}$ couplings ( $2-25 \mathrm{~Hz}$, Tables 2.8 and 2.9 ) ${ }^{16,23}$. Experiments that probe these couplings include the CH COLOC ${ }^{24}$ (correlation via long range couplings) with carbon-13 detection (Fig. 2.16) and HC HMBC (heteronuclear multiple bond coherence) with the much more sensitive proton detection (Fig. 2.17) ${ }^{17}$.

a

Figure 2.16. CH COLOC experiment of $\alpha$-pinene $\left[\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}, 10 \% \mathrm{v} / \mathrm{v}, 25^{\circ} \mathrm{C}, 50 \mathrm{MHz}\right.$ for ${ }^{13} \mathrm{C}, 200 \mathrm{MHz}$ for ${ }^{1} \mathrm{H}$, 256 scans and experiments]. (a) stacked plot of the section between $\delta_{\mathrm{C}}=20.9$ and $47.2\left({ }^{13} \mathrm{C}\right)$ and $\delta_{H}=0.85$ and $2.34\left({ }^{3} H\right.$ ); (b) contour plot of (a). One-dimensional ${ }^{13} \mathrm{C}$ and ${ }^{1} H$ NMR spectra for this section are shown aligned with the abscissa and ordinate of the contour plot. ${ }^{1} J_{\mathrm{CH}}$ correlation signals which are already known from the CH COSY study (Fig. 2.14) and have not been suppressed, are indicated by circles

These two-dimensional CH shift correlations indicate CH relationships through two and more bonds (predominantly ${ }^{2} J_{\mathrm{CH}}$ and ${ }^{3} J_{\mathrm{CH}}$ connectivities) in addition to more or less suppressed ${ }^{1} J_{\mathrm{CH}}$ relationships which are in any case established from the CH COSY contour diagram. Format and analysis of the CH COLOC or HMBC plots correspond to those of a CH COSY or HSQC experiment, as is shown for $\alpha$-pinene (1) in Figs. 2.14-2.17.
When trying to establish the CH relationships of a carbon atom (exemplified by the quaternary C at $\delta_{\mathrm{C}}=38.0$ in Figs. 2.16 and 2.17), the chemical shifts of protons at a distance of two or three bonds are found parallel to the proton axis (e.g. $\delta_{H}=0.85$ (0.84), 1.16 and 1.27 in Figs. 2.16 and 2.17). It is also possible to take a proton signal as the starting point and from the cross signals parallel to the carbon axis to read off the shifts of the C atoms two or three bonds distant respectively. Thus, for example, one deduces that the methyl protons at $\delta_{H}=0.84$ and 1.27 are two and three bonds apart from the C atoms at $\delta_{\mathrm{C}}=38.0,40.9$ and 47.2 as illustrated by the partial structures 1a and 1b in Fig. 2.17. CH correlation signals due to methyl protons prove to be especially reliable, as do trans CH relationships over three bonds, e.g. between $\delta_{H}=1.16$ and $\delta_{\mathrm{C}}=38.0$ in Figs. 2.16 and 2.17, in contrast to the missing cis relationship between $\delta_{H}=2.34$ and $\delta_{\mathrm{C}}=38.0$ (partial structures $\mathbf{1 d}$ and 1 g in Fig. 2.17) due to the smaller coupling constant to which the experiment was not adjusted.

Figure 2.16 (c). CH COLOC experiment of $\alpha$-pinene $\left[\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}, 10 \% \mathrm{v} / \mathrm{v}, 25^{\circ} \mathrm{C}, 50 \mathrm{MHz}\right.$ for ${ }^{13} \mathrm{C}, 200 \mathrm{MHz}$ for ${ }^{\mathrm{h}} \mathrm{H}, 256$ scans and experiments], complete contour plot (caption on previous page)

Figure 2.17. HC HMBC experiment of $\alpha$-pinene $\left[\left(\mathrm{CDCl}_{3}, 5 \% \mathrm{v} / \mathrm{v}, 25^{\circ} \mathrm{C}, 125 \mathrm{MHz}\right.\right.$ for ${ }^{13} \mathrm{C}, 500 \mathrm{MHz}$ for ${ }^{1} \mathrm{H}, 16$ scans, 256 experiments, contour plot]. This experiment gives the same information as Fig. 2.16 within 24 min instead of 8 hrs required for the CH -COLOC in Fig. 2.16 due to higher sensitivity because of proton detection and stronger magnetic field. Deviations of proton shifts from those in Fig. 2.16 arise from the change of the solvent. The methylene protons collapsing in Fig. 2.16 at $\delta_{H}=2.19(200 \mathrm{MHz})$ display in this experiment an $A B$ system with $\delta_{A}=2.17$ and $\delta_{B}=2.21(500 \mathrm{MHz})$

### 2.3 Relative configuration and conformation

### 2.3.1 HH Coupling constants

Vicinal coupling constants ${ }^{3} J_{H H}$ indicate very clearly the relative configuration of the coupling protons. Their contribution depends, according to the Karplus-Conroy equation ${ }^{2,3}$,

$$
\begin{equation*}
{ }^{3} J_{H H}=a \cos ^{2} \varphi-0.28 \quad \text { (up to } \varphi=90^{\circ}: a \approx 10 ; \text { above } \varphi=90^{\circ}: a \approx 15 \text { ) } \tag{2}
\end{equation*}
$$

on the dihedral angle $\varphi$, enclosed by the CH bonds as shown in Fig. 2.18, which sketches the Kar-plus-Conroy curves for dihedral angles from 0 to $180^{\circ}$. Experimental values correspond to those given by the curve shown; deviations are up to 3 Hz ; electronegative substituents on the coupling path, for example, reduce the magnitude of ${ }^{3} J_{H H}$.

Figure 2.18. Vicinal HH coupling constants ${ }^{3} J_{H H}$ as a function of the dihedral angle $\varphi$ of the CH bonds concerned (Karplus-Conroy relationship)

For the stable conformers $\mathbf{1 3 a - c}$ of a substituted ethane the vicinal HH coupling constants $J_{\mathrm{s}} \approx 3 \mathrm{~Hz}$ for syn-protons and $J_{a} \approx 15 \mathrm{~Hz}$ for anti-protons can be derived from Fig. 2.18. If there is rotation around the $\mathrm{C}-\mathrm{C}$ single bond, the coupling protons pass through the $\operatorname{syn}$ configuration twice and the anti configuration once.

Therefore, from

$$
\begin{equation*}
{ }^{3} J_{\text {(average })}=\left({ }^{2} J_{\mathrm{s}}+J_{a}\right) / 3=21 / 3=7 \mathrm{~Hz} \tag{3}
\end{equation*}
$$

an average coupling constant of about 7 Hz is obtained. This coupling constant characterises alkyl groups with unimpeded rotation (cf. Figs 1.2 and 2.19).
Ethyl dibromodihydrocinnamate (14), for example, can form the three staggered conformers 14a-c by rotation around the CC single bond $\alpha$ to the phenyl ring.

The ${ }^{l} H$ NMR spectrum (Fig. 2.19) displays an $A B$ system for the protons adjacent to this bond; the coupling constant ${ }^{3} J_{A B}-12 \mathrm{~Hz}$. From this can be deduced first that the dihedral angle $\varphi$ between the CH bonds is about $180^{\circ}$, second that conformer $\mathbf{1 4 b}$ with minimised steric repulsion between the substituents predominates and third that there is restricted rotation around this CC bond.

Figure 2.19. ${ }^{1} \mathrm{H}$ NMR spectrum of ethyl dibromodihydrocinnamate (14) [ $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 90 \mathrm{MHz}, \mathrm{CW}$ recording]

The relative configuration of the protons which is deduced from the coupling constant ${ }^{3} J_{A B}$ confirms the conformation of this part of the structure of this molecule. On the other hand, the ${ }^{3} J_{H H}$ coupling constant of the ethyl group attached to oxygen ( 7 Hz , Fig. 2.19) reflects equal populations of all stable conformers around the CC bond of this ethyl group.
The ${ }^{3} J_{H H}$ couplings shown in Table 2.10 verify the Karplus-Conroy equation 2 (Fig. 2.18) for rigid systems. Hence in cyclopropane the relationship ${ }^{3} J_{H H(c i s)}>{ }^{3} J_{H H(t r a n s)}$ holds, because cis-cyclopropane protons enclose a dihedral angle of about $0^{\circ}$, in contrast to an angle of ca $145^{\circ}$ between trans protons, as shown by Dreiding models. Vicinal protons in cyclobutane, cyclopentane, norbornane and norbornene behave in an analogous way with larger cis, endo-endo and exo-exo couplings, respectively (Table 2.10).
Substituent effects (electronegativity, configuration) influence these coupling constants in four-, five- and seven-membered ring systems, sometimes reversing the cis-trans relationship ${ }^{2,3}$, so that other NMR methods of structure elucidation, e.g. NOE difference spectra (see Section 2.3.5), are needed to provide conclusive results. However, the coupling constants of vicinal protons in cyclohexane and its heterocyclic analogues (pyranoses, piperidines) and also in alkenes (Table 2.10) are particularly informative.
Neighbouring diaxial protons of cyclohexane can be clearly identified by their large coupling constants ( ${ }^{3} J_{a a} \approx 11-13 \mathrm{~Hz}$, Table 2.10 ) which contrast with those of protons in diequatorial or axialequatorial configurations $\left({ }^{3} J_{e e} \approx{ }^{3} J_{a e} \approx 2-4 \mathrm{~Hz}\right.$ ). Similar relationships hold for pyranosides as oxygen hetero analogues of cyclohexane, wherein the electronegative $O$ atoms reduce the magnitude of the coupling constants ( ${ }^{3} J_{a a} \approx 9 \mathrm{~Hz},{ }^{3} J_{a e} \approx 4 \mathrm{~Hz}$, Table 2.10). These relationships are used for elucidation of the configuration of substituted cyclohexanes (problem 37), cyclohexenes (problems 12 and 35), terpenes (problems 47, 48, 50 and 51), flavans (problem 10) and glycosides (problem 45, Table 2.10 ). In these cases also, the relative configuration of the protons which is deduced from the ${ }^{3} J_{H H}$ coupling constant reveals the conformation of the six-membered rings. Thus the coupling constant 9 Hz of the protons in positions 1 and 2 of the methyl- $\beta$-D-glucopyranoside 15 determines not only the diaxial configuration of the coupling protons but also the ${ }^{4} \mathrm{C}_{1}$ conformation of the pyranose ring. If the sterically more crowded ${ }^{1} \mathrm{C}_{4}$ conformation (exclusively with axial substituents) were present then a diequatorial coupling ( 4 Hz ) of protons $1-H$ and 2-H would be observed. If the conformers were inverting ( $50: 50$ population of the ${ }^{4} \mathrm{C}_{1}$ and ${ }^{1} \mathrm{C}_{4}$ conformers), then the coupling constant would be the average ( 6.5 Hz ).

The couplings of vicinal protons in 1,2-disubstituted alkenes lie in the range $6-12 \mathrm{~Hz}$ for cis protons (dihedral angle $0^{\circ}$ ) and 12-17 Hz for trans protons (dihedral angle $180^{\circ}$ ), thus also following the Karplus-Conroy equation. Typical examples are the alkene proton $A B$ systems of coumarin (16a, cis) and trans-cinnamic acid ( $\mathbf{1 6 b}$ ), and of the cis-trans isomers $\mathbf{1 7 a}$ and $\mathbf{b}$ of ethyl isopentenyl ether, in addition to those in problems $3,4,8,11,13$ and 38.

Cyclopropanes

### 2.3.2 CH Coupling constants

Geminal CH coupling constants ${ }^{2} J_{\mathrm{CH}}$ reflect the configuration of electronegative substituents in molecules with a defined geometry such as pyranose and alkenes ${ }^{16}$. If an electronegative substituent is attached cis with respect to the coupling proton, then the coupling constant ${ }^{2} J_{\mathrm{C} H}$ has a higher negative value; if it is located trans to the coupling proton, then ${ }^{2} J_{\mathrm{CH}}$ is positive and has a lower value; this is illustrated by $\beta$ - and $\alpha$-D-glucopyranose (18a and $\mathbf{b}$ ) and by bromoethene (19).

18a

18b

19

Vicinal CH coupling constants ${ }^{3} J_{\mathrm{CH}}$ resemble vicinal $H H$ coupling constants in the way that they depend on the cosine ${ }^{2}$ of the dihedral angle $\varphi$ between the CC bond to the coupled C atom and the CH bond to the coupled proton ${ }^{16}$ (cf. Fig. 2.16), as illustrated by the Newman projections of the conformers 20a-c of a propane fragment.

It follows from this that where there is equal population of all conformers in an alkyl group (free rotation about the CC single bond) then an averaged coupling constant ${ }^{3} J_{\mathrm{CH}}=\left(2 J_{s y n}+J_{\text {anii }}\right) / 3$ of between 4 and 5 Hz can be predicted, and that vicinal CH coupling constants ${ }^{3} J_{\mathrm{CH}}$ have values about two thirds of those of vicinal protons, ${ }^{3} J_{H H}{ }^{16}$.
Like ${ }^{3} J_{H H}$ couplings, ${ }^{3} J_{\mathrm{CH}}$ couplings give conclusive information concerning the relative configuration of C and $H$ as coupled nuclei in cyclohexane and pyranose rings and in alkenes (Table 2.11). Substituted cyclohexanes have ${ }^{3} J_{\mathrm{CH}} \approx 2-4 \mathrm{~Hz}$ for cis and $8-9 \mathrm{~Hz}$ for trans configurations of the coupling partners; electronegative $O H$ groups on the coupling path reduce the magnitude of ${ }^{3} J_{\mathrm{CH}}$ in pyranoses (Table 2.11). When deducing the configurations of multi-substituted alkenes, e.g. in solving problem 19, the ${ }^{3} J_{\mathrm{CH}}$ couplings of the alkenes in Table 2.11 are useful.
${ }^{3} J_{\text {CH(trans) }}>{ }^{3} J_{\text {CH(cis) }}$ holds throughout. Electronegative substituents on the coupling carbon atom increase the $J$-value, whilst reducing it on the coupling path. Moreover, ${ }^{3} J_{C H}$ reflects changes in the bonding state (carbon hybridisation) and also steric hindrance (impeding coplanarity), as further examples in Table 2.11 show.

Table 2.11. ${ }^{3} J_{\mathrm{CH}}$ coupling constants $(\mathrm{Hz})$ and relative configuration ${ }^{16}$. The coupling path is shown in bold
Cycohexane derivatives and pyranosas

### 2.3.3 NH Coupling constants

The relationship beiween ${ }^{3} J_{N H}$ and the dihedral angle of the coupling nuciei, of the type that applies to vicinal couplings of ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$, very rarely permits specific configurational assignments because the values ( ${ }^{3} J_{\mathrm{N} H}<5 \mathrm{~Hz}$ ) are too small ${ }^{7}$. In contrast, geminal couplings ${ }^{2} J_{\mathrm{N} H}$ distinguish the relative configurations of aldimines very clearly. Thus, anti-furan-2-aldoxime (21a) shows a considerably larger ${ }^{2} J_{\mathrm{N} H}$ coupling than does the syn isomer $21 \mathbf{b}$; evidently in imines the nonbonding electron pair cis to the CH bond of the coupled proton has the effect of producing a high negative contribution to the geminal NH coupling.

### 2.3.4 ${ }^{13} \mathrm{C}$ Chemical shifts

A carbon atom in an alkyl group is shielded by a substituent in the $\gamma$-position, that is, it experiences a smaller ${ }^{13} \mathrm{C}$ chemical shift or a negative substituent effect ${ }^{4-6}$. This originates from a sterically induced polarisation of the CH bond: the van der Waals radii of the substituent and of the hydrogen atom on the $\gamma$-C overlap; as a result, the $\sigma$-bonding electrons are moved from $H$ towards the $\gamma$ C atom; the higher electron density on this C atom will cause shielding. As the Newman projections 22a-c show, a distinction can be made between the stronger $\gamma-s y n$ and the weaker $\gamma$-anti effect. If there is free rotation, then the effects are averaged according to the usual expression, $\left(2 \gamma_{\text {syn }}+\gamma_{\text {ant }}\right) / 3$, and one observes a negative $\gamma$-substituent effect of -2.5 to $-3.5 \mathrm{ppm}^{4-6}$, which is typical for alkyl groups.

In rigid molecules, strong $\gamma$-effects on the ${ }^{13} \mathrm{C}$ shift (up to 10 ppm ) allow the different configurational isomers to be distinguished unequivocally, as cis- and trans-3- and -4-methylcyclohexanol (Table 2.12) illustrate perfectly: if the OH group is positioned axial, then its van der Waals repulsion of a coaxial $H$ atom shields the attached C atom in the $\gamma$-position. 1,3-Diaxial relationships between substituents and $H$ atoms in cyclohexane, norbornane and pyranosides shield the affected C atoms, generating smaller ${ }^{13} \mathrm{C}$ shifts than for isomers with equatorial substituents (Table 2.12).
The ${ }^{13} \mathrm{C}$ chemical shift thus reveals the relative configuration of substituents in molecules with a definite conformation, e.g. the axial position of the OH group in trans-3-methylcyclohexanol, cis4 -methylcyclohexanol, $\beta$-D-arabinopyranose and $\alpha$-D-xylopyranose (Table 2.12, p. 50). It turns out, in addition, that these compounds also take on the conformations shown in Table 2.12 (arabinopyranose, ${ }^{1} \mathrm{C}_{4}$; the others, ${ }^{4} \mathrm{C}_{1}$ ); if they occurred as the other conformers, then the OH groups on $\mathrm{C}-1$ in these molecules would be equatorial with the result that larger shifts for $\mathrm{C}-1, \mathrm{C}-3$ and $\mathrm{C}-5$ would be recorded. A ring inversion ( $50: 50$ population of both conformers) would result in an average ${ }^{13} \mathrm{C}$ shift.
Compared with ${ }^{\prime} H$ chemical shifts, ${ }^{13} \mathrm{C}$ shifts are more sensitive to steric effectis, as a comparisun of the ${ }^{1} \mathrm{H}$ and the ${ }^{13} \mathrm{C}$ NMR spectra (cis- and trans-4-tert-butylcyclohexanol 23) in Fig. 2.20 shows. The polarisation through space of the $\gamma$ - CH bond by the axial OH group in the cis isomer 23b shields C-1 by -5.6 and $\mathrm{C}-3$ by $-4.8 \mathrm{ppm}\left(\gamma\right.$-effect). In contrast the ${ }^{I} H$ shifts reflect the considerably smaller anisotropic effect (see Section 2.5.1) of cyclohexane bonds: equatorial substituents (in this case $H$ and OH ) display larger shifts than axial substituents; the equatorial $1-H$ in the cis-isomer 23b ( $\delta_{H}=3.92$ ) has a larger shift than the axial $1-H$ in the trans-compound 23a ( $\delta_{H}=3.40$ ); the difference is significantly smaller ( -0.52 ppm ) than the $\gamma$-effect on the ${ }^{13} \mathrm{C}$ shifts (ca -5 ppm ). Both spectra additionally demonstrate the value of NMR spectroscopy for quantitative analysis of mixturcs by measuring integral levels or signal intensities, respectively, Finally, $\mathrm{D}_{2} \mathrm{O}$ exchange eliminates the OH protons and their couplings from the ${ }^{l} H$ NMR spectra (Fig. 2.20d).

Figure 2.20. NMR spectra of trans-and cis-4-tert-butylcyclohexanol (23a and 23b) [(CD $\left.\mathrm{CD}_{3}\right)_{2} \mathrm{CO}, 25^{\circ} \mathrm{C}, 400 \mathrm{MHz}$ for ${ }^{1} \mathrm{H}, 100 \mathrm{MHz}$ for ${ }^{13} \mathrm{C}$ ]. (a) ${ }^{1} \mathrm{H}$ decoupled ${ }^{13} \mathrm{C}$ NMR spectrum (NOE suppressed, comparable signal intensities); (b) ${ }^{1} \mathrm{H}$ NMR spectrum; (c) section of (b) $\left(\delta_{H}=3-4\right)$ with integrals; (d) partial spectrum (c) following $\mathrm{D}_{2} \mathrm{O}$ exchange. The integrals (c) and the ${ }^{13} \mathrm{C}$ signal intensities (a) give the trans: cis isomer ratio $71: 29$. Proton $1-H$ $\left(\delta_{H}=3.40\right)$ in the trans isomer 23a forms a triplet ( 10.8 Hz , two anti protons in $2,2^{\prime}$-positions) of quartets ( 4.3 Hz , two syn protons in 2,2'-positions and the OH proton as additional coupling partner); following $\mathrm{D}_{2} \mathrm{O}$ exchange a triplet ( 10.8 Hz ) of triplets ( 4.3 Hz ) appears, because the coupling to OH is missing. In the cis isomer 23b proton 1-H forms a sextet ( 3.0 Hz , four synclinal protons in $2,2^{\prime}$-positions and OH ) which appears as a quintet following $\mathrm{D}_{2} \mathrm{O}$ exchange because the coupling to OH is then lost

Table 2.12. ${ }^{13} \mathrm{C}$ chemical shifts ( $\delta_{C}$ ) and relative configurations of cycloalkanes, pyranoses and alkenes (application of $\gamma$-effects) ${ }^{4-6}$. The shifts which are printed in boldface reflect $\gamma$-effects on $C$ atoms in the corresponding isomer pairs

| cis- | $22.5 \mathrm{H}_{3} \mathrm{C} \overbrace{31.7}^{34.8} \mathrm{~m}_{44.0}^{24.4} \mathrm{~T}_{70.5}^{34.4} \mathrm{OH}$ | 3-Methyicyciohexanol |  | trans- |
| :---: | :---: | :---: | :---: | :---: |
| trans- |  | 4-Methylcyclohexanol |  | cis- |
| $\alpha$ - |  | D-Arabinopyranose ( ${ }^{1} \mathrm{C}_{4}$ conformation) |  | $\beta$ - |
| $\beta$ - |  | D-Xylopyranose ( ${ }^{4} \mathrm{C}_{1}$ conformation) |  | $\alpha-$ |
| exo- |  | 2-Methyinorbornane |  | endo- |
| exo- |  | 2-Norbornanol |  | endo- |
| trans- |  | $\mathrm{H}_{3}$ <br> 2-Hexene |  | cis- |

The $\gamma$-effect on the ${ }^{13} \mathrm{C}$ shift also causes the difference between $(E)$ - and $(Z)$-configurations of the alkyl groups in alkenes. Here the $\mathrm{C}-\alpha$ atom shift responds most clearly to the double bond configurational change: these atoms in cis-alkyl groups occupy $\gamma$-positions with respect to each other; they are eclipsed, enclosing a dihedral angle of $0^{\circ}$, which leads to an especially strong van der Waals interaction and a correspondingly strong shielding of the ${ }^{13} \mathrm{C}$ nucleus. For this reason, the relationship $\left[\delta_{\text {trans }}>\delta_{\text {cis }}\right.$ ] holds for the $\alpha-\mathrm{C}$ atoms of alkenes, as shown in Table 2.12 for $(E)$ - and $(Z)$-2-hexene. The ${ }^{13} \mathrm{C}$ shifts of the doubly bonded carbon atoms behave similarly, although the effect is considerably smaller.
$\alpha, \beta$-Unsaturated carbonyl compounds show smaller ${ }^{13} \mathrm{C}$ shifts than comparable saturated compounds ${ }^{4-6}$, provided that their carbonyl and CC double bonds are coplanar. If steric hindrance prevents coplanarity, conjugation is reduced and so larger ${ }^{13} \mathrm{C}$ shifts are observed. In $\alpha, \beta$-unsaturated carbonyl compounds such as benzophenones and benzoic acid derivatives the twist angle $\theta$ between the carbonyl double bond and the remaining $\pi$-system can be read off and hence the conformation derived from the ${ }^{13} \mathrm{C}$ shift ${ }^{25}$, as several benzoic acid esters (24) illustrate.
plane of the benzenoid ring--

### 2.3.5 NOE Difference spectra

Changes in signal intensities caused by spin decoupling (double resonance) are referred to as the nuclear Overhauser effect (NOE) ${ }^{3,26}$. In proton decoupling of ${ }^{13} \mathrm{C}$ NMR spectra, the NOE increases the intensity of the signals generated by the C atoms which are bonded to hydrogen by up to $300 \%$; almost all techniques for measuring ${ }^{13} \mathrm{C}$ NMR spectra exploit this gain in sensitivity ${ }^{2-6}$. If in recording ${ }^{l} H$ NMR spectra certain proton resonances are decoupled (homonuclear spin decoupling), then the changes in intensity due to the NOE are considerably smaller (much less than $50 \%$ ). For the assignment of configuration it is useful that, during perturbing the equilibrium population of a particular proton by irradiating it for long enough, other protons in the vicinity may be affected although not necessarily coupled with this proton. As a result of molecular motion and the dipolar relaxation processes associated with it, the populations of energy levels of the protons change ${ }^{3,26}$; their signal intensities change accordingly (NOE). For example, if the signal intensity of one proton increases during irradiation of another, then these protons must be positioned close to one another in the molecule, irrespective of the number of bonds which separate them.
NOE difference spectroscopy has proved to be a useful method for studying the spatial proximity of protons in a molecule ${ }^{27}$. In this experiment the ${ }^{1} H$ NMR spectrum is recorded during the irradiation of a particular proton (measurement 1); an additional measurement with an irradiation frequency which lies far away (the 'off-resonance' experiment) but is otherwise subject to the same conditions, is then the basis for a comparison (reference measurement 2). The difference between the two measurements provides the NOE difference spectrum, in which only those signals are shown whose intensities are increased (positive signal) or decreased (negative signal) by NOE. Figure 2.21 illustrates NOE difference spectroscopy with $\alpha$-pinene (1): irradiation of the methyl protons at $\delta_{H}=1.27$ (experiment c) gives a significant NOE on the proton at $\delta_{H}=2.34$; if for comparison, the methyl protons with $\delta_{H}=0.85$ are perturbed (experiment $\mathbf{b}$ ), then no NOE is observed at $\delta_{H}=2.34$. From this the proximity of the methylene $-H$ atom at $\delta_{H}=2.34$ and the methyl group at 1.27 in $\alpha$-pinene is detected. In addition, both experiments confirm the assignment of the methyl protons to the signals at $\delta_{H}=0.85$ and 1.27. A negative NOE, as on the protons at $\delta_{H}=$ 1.16 in experiment $\mathbf{c}$, is the result of coupling, e.g. in the case of the geminal relationship with the affected proton at $\delta_{H}=2.34$. Further applications of NOE difference spectroscopy are provided in problems 29, 33, 34, 36, 44, 48, and 50-54.

Figure 2.21. HH NOE difference spectra (b, c) and $H H$ NOESY diagram (d) of $\alpha$-pinene (1) with ${ }^{1} H$ NMR spectrum (a) for comparison [ $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}, 10 \% \mathrm{v} / \mathrm{v}, 25^{\circ} \mathrm{C}, 200 \mathrm{MHz}$, section from $\delta_{H}=0.85$ to 2.34 ]. Vertical arrows in (b) and (c) indicate the irradiation frequencies; in the HH NOESY plot (d), cross-signals linked by a dotted line show the NOE detected in (c)

### 2.3.6 HH NOESY and ROESY

The $H H$ COSY sequence for ascertaining the $H H$ connectivities also changes the populations of the energy levels, leading to NOEs. Thus, the $H H$ COSY experiment has been modified to pulse sequences such as $H H$ NOESY ${ }^{17,28}$ which allows a two-dimensional detection of NOEs. The result of such measurements is shown in the $H H$ NOESY plot with square symmetry (Fig. 2.21d) which is evaluated in the same way as $H H$ COSY. Fig. 2.21d shows by the cross signals at $\delta_{H}=$ 2.34 and 1.27 that the appropriate protons in $\alpha$-pinene (1) are close to one another; the experiment also illustrates that the $H H$ COSY cross signals (due to through-bond coupling) are not completely suppressed. Therefore, before evaluating a two-dimensional NOE experiment, it is essential to know the $H H$ connectivities from the $H H$ COSY plot.
The NOESY sequence sensitively reacts towards the change of the sign of NOEs depending on molecular motion. The ROESY experiment ${ }^{2,17}$ involving an isotropic mixture of magnetisations by spin-locking detects NOEs without these limitations. Thus, the proximity of the methyl protons in $\alpha$-pinene ( $\left(\delta_{H}=0.84\right.$ in $\left.\mathrm{CDCl}_{3}\right)$ to the exo-methylene proton ( $\delta_{H}=2.17$ ) is additionally indicated and assigned in the ROESY experiment (Fig. 2.22). Problems 46 and 55 exemplify further applications.

Figure 2.22. HH ROESY diagram of $\alpha$-pinene (1) with ${ }^{1} H$ NMR spectrum $\left[\mathrm{CDCl}_{3}, 10 \% \mathrm{v} / \mathrm{v}, 25{ }^{\circ} \mathrm{C}, 500 \mathrm{MHz}\right.$, section from $\delta_{H}=0.84$ to 2.34$]$. Deviations of chemical shifts from those in other experiments (Figs. 2.14, 2.16) arise from solvent effects; the methylene protons collapsing in Fig. 2.21 at $\delta_{H}=2.19(200 \mathrm{MHz})$ display in this experiment an $A B$ system with $\delta_{A}=2.17$ and $\delta_{B}=2.21(500 \mathrm{MHz})$

A comparison of the methods of proton-proton NOE detection has shown that two-dimensional NOE detection such as NOESY and ROESY are better suited to the investigation of the stereochemistry of biopolymers whereas for small- to medium-sized molecules (up to 30 C atoms) NOE difference spectroscopy is less time consuming, more selective and thus more conclusive.

### 2.4 Absolute configuration

### 2.4.1 Diastereotopism

Where both $H$ atoms of a methylene group cannot be brought into a chemically identical position by rotation or by any other movement of symmetry, they are said to be diastereotopic ${ }^{2,3}$. The precise meaning of diastereotopism is best illustrated by means of an example, that of methylene protons $H^{A}$ and $H^{B}$ of glycerol (25). Where there is free rotation about the CC bonds, the terminal $\mathrm{CH}_{2} \mathrm{OH}$ groups rotate through three stable conformations. They are best shown as Newman projections (25a-c) and the chemical environments of the $\mathrm{CH}_{2} \mathrm{O}$ protons, $H^{A}$ and $H^{B}$ are examined with particular reference to geminal and synclinal neighbours.

It can be seen that the six possible near-neighbour relationships are all different. If rotation were frozen, then three different shifts would be measured for $H^{A}$ and $H^{B}$ in each of the conformers $\mathbf{a}, \mathbf{b}$ and $\mathbf{c}\left(\delta_{1}, \delta_{2}\right.$ and $\delta_{3}$ for $H^{i}, \delta_{4}, \delta_{5}$ and $\delta_{6}$ for $\left.H^{B}\right)$. If there is free rotation at room temperature and if $\chi_{\mathrm{a}}, \chi_{\mathrm{b}}$ and $\chi_{\mathrm{c}}$ are the populations of conformers $\mathbf{a}, \mathbf{b}$ and $\mathbf{c}$, then according to the equations 4 ,

$$
\begin{equation*}
\delta_{\mathrm{A}}=\chi_{\mathrm{a}} \delta_{1}+\chi_{\mathrm{b}} \delta_{2}+\chi_{\mathrm{c}} \delta_{3} \quad \text { and } \quad \delta_{B}=\chi_{\mathrm{a}} \delta_{4}+\chi_{\mathrm{b}} \delta_{\mathrm{S}}+\chi_{\mathrm{c}} \delta_{\sigma} \tag{4}
\end{equation*}
$$

different average shifts $\delta_{A}$ and $\delta_{B}$ are recorded which remain differentiated when all three conformations occur with equal population ( $\chi_{\mathrm{a}}=\chi_{\mathrm{b}}=\chi_{\mathrm{c}}=1 / 3$ ). Chemical equivalence of such protons would be purely coincidental.
Figure 2.23 shows the diastereotopism of the methylene protons ( $\mathrm{CH} H^{4} H^{B} \mathrm{OD}$ ) of glycerol (25) in $\mathrm{D}_{2} \mathrm{O}$ solution ( OH exchanged to OD ); it has a value of $\delta_{B}-\delta_{A}=0.09$. The spectrum displays an $(A B)_{2} C$ system for the symmetric constitution, $\left(\mathrm{CH}^{A} H^{B} \mathrm{OD}\right)_{2} \mathrm{CH} H^{C} \mathrm{OD}$, of the molecule with geminal coupling ${ }^{2} J_{A B}=11.6 \mathrm{~Hz}$ and the vicinal coupling constants ${ }^{3} J_{A C}=6.4$ and ${ }^{3} J_{B C}=4.5 \mathrm{~Hz}$. The unequal ${ }^{3} J$ couplings provide evidence against the unhindered rotation about the CC bonds of glycerol and indicate instead that conformer a or $\mathbf{c}$ predominates with a smaller interaction of the substituents compared to $\mathbf{b}$.
25

$\delta_{A}=3.50$
$\delta_{B}=3.59$
$\delta_{c}=3.73$

Figure 2.23. ${ }^{1} \mathrm{H}$ NMR spectrum of glycerol $\left[25, \mathrm{D}_{2} \mathrm{O}, 10 \%, 25^{\circ} \mathrm{C}, 400 \mathrm{MHz}\right]$

Diastereotopism indicates prochirality, as exemplified by glycerol (25, Fig. 2.23). Other examples of this include diethylacetals, in which the $\mathrm{OCH}_{2}$ protons are diastereotopic on account of the prochiral acetal-C atoms, thus forming $A B$ systems of quartets because of coupling with the methyl protons.
The Newman projections 25a-c draw attention to the fact that the central C atom, as seen from the terminal $\mathrm{CH}_{2} \mathrm{OD}$ groups, appears asymmetric. It follows from this that diastereotopism is also a way of probing ncighbouring asymmetric C atoms. Thus the methyl groups of the isopropyl residues in $D$ - or $L$-valine (26) are diastereotopic and so show different ${ }^{1} H$ and ${ }^{13} \mathrm{C}$ shifts, although these cannot be individually assigned to the two groups. In chiral alcohols of the type 27 the diastereotopism of the isopropyl-C nucleus increases with the size of the alkyl residues (methyl < isopropyl < tert-butyl) ${ }^{29}$.

26

27

H

If a molecule contains several asymmetric C atoms, then the diastereomers show diastereotopic shifts. Clionasterol (28a) and sitosterol (28b) for example, are two steroids that differ only in the absolute configuration at one carbon atom, C-24 ${ }^{30}$. Differing shifts of ${ }^{13} \mathrm{C}$ nuclei close to this asymmetric C atom in 28a and $\mathbf{b}$ identify the two diastereomers including the absolute configuration of $\mathrm{C}-24$ in both. The absolute configurations of carboxylic acids in pyrrolizidine ester alkaloids are also reflected in diastereotopic ${ }^{1} H$ and ${ }^{13} \mathrm{C}$ shifts ${ }^{31}$, which is used in solving problem 54.

28a Clionasterol (24S)

28b Sitosterol (24R)

### 2.4.2 Chiral shift reagents (ee determination)

The presence of asymmetric C atoms in a molecule may, of course, be indicated by diastereotopic shifts and absolute configurations may, as already shown, be determined empirically by comparison of diastereotopic shifts ${ }^{30,31}$. However, enantiomers are not differentiated in the NMR spectrum. The spectrum gives no indication as to whether a chiral compound exists in a racemic form or as a pure enantiomer.
Nevertheless, it is possible to convert a racemic sample with chiral reagents into diastereomers or simply to dissolve it in an enantiomerically pure solvent $\boldsymbol{R}$ or $\boldsymbol{S}$; following this process, solvation diastereomers arise from the racemate ( $R \mathrm{P}+S \mathrm{P}$ ) of the sample P , e.g. $R: R \mathrm{P}$ and $\boldsymbol{R}: S \mathrm{P}$, in which the enantiomers are recognisable because of their different shifts. Compounds with groups which influence the chemical shift because of their anisotropy effect (see Sections 2.5.1 and 2.5.2) are suitable for use as chiral solvents, e.g. 1-phenylethylamine and 2,2,2-trifluoro-1-phenylethanol ${ }^{32}$.
A reliable method of checking the enantiomeric purity by means of NMR uses europium(III) or praseodymium(III) chelates of type 29 as chiral shift reagents ${ }^{33}$. With a racemic sample, these form diastereomeric europium(III) or praseodymium(III) chelates, in which the shifts of the two enantiomers are different. Different signals for $R$ and $S$ will be observed only for those nuclei in immediate proximity to a group capable of coordination ( $\mathrm{OH}, \mathrm{NH}, \mathrm{C}=\mathrm{O}$ ). The separation of the signals increases with increasing concentration of the shift reagent; unfortunately, line broadening of signals due to the paramagnetic ion increases likewise with an increase in concentration, which limits the amount of shift reagent which may be used. Figure 2.24 shows the determination of an enantiomeric excess (ee) following the equation 5

$$
\begin{equation*}
e e=\frac{R-S}{R+S} \times 100(\%) \tag{5}
\end{equation*}
$$

for 1-phenylethanol (30) by ${ }^{l} H$ and ${ }^{13} \mathrm{C}$ NMR, using tris[3-(heptafluoropropylhydroxymethylene)-D-camphorato]praseodymium(III) (29b) as a chiral shift reagent.

Figure 2.24. Determination of the enantiomeric excess of 1-phenylethanol [ $30,0.1 \mathrm{mmol}$ in $0.3 \mathrm{ml} \mathrm{CDCl} 3,25^{\circ} \mathrm{C}$ ] by addition of the chiral praseodymium chelate $\mathbf{2 9 b}(0.1 \mathrm{mmol})$. ( $\mathbf{a}, \mathbf{b}$ ) ${ }^{1} \mathrm{H}$ NMR spectra ( 400 MHz ), (a) without and (b) with the shift reagent 29b. (c, d) ${ }^{13} \mathrm{C}$ NMR spectra ( 100 MHz ), (c) without and (d) with the shift reagent 29b. In the ${ }^{13} \mathrm{C}$ NMR spectrum (d) only the $\mathrm{C}-\alpha$ atoms of enantiomers $30 R$ and 30 S are resolved. The ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ signals of the phenyl residues are not shifted; these are not shown for reasons of space. The evaluation of the integrals gives $73 \% R$ and $27 \%$ S, i.e. an enantiomeric excess (ee) of $46 \%$

### 2.5 Intra- and intermolecular interactions

### 2.5.1 Anisotropic effects

The chemical shift of a nucleus depends in part on its spatial position in relation to a bond or a bonding system. The knowledge of such anisotropic effects ${ }^{2,3}$ is useful in structure elucidation. An example of the anisotropic effect would be the fact that axial nuclei in cyclohexane almost always show smaller ${ }^{1} \mathrm{H}$ shifts than equatorial nuclei on the same C atom (illustrated in the solutions to problems $37,47,48,50$ and 51 ). The $\gamma$-effect also contributes to the corresponding behaviour of ${ }^{13} \mathrm{C}$ nuclei (see Section 2.3.4).

Multiple bonds are revealed clearly by anisotropic effects. Textbook examples include alkynes, shielded along the $\mathrm{C} \equiv \mathrm{C}$ triple bond, and alkenes and carbonyl compounds, where the nuclei are deshielded in the plane of the $\mathrm{C}=\mathrm{C}$ and $\mathrm{C}=\mathrm{O}$ double bonds, respectively ${ }^{2,3}$. One criterion for distinguishing methyl groups attached to the double bond of pulegone (31), for example, is the carbonyl anisotropic effect.

### 2.5.2 Ring current of aromatic compounds

Benzene shows a considerably larger ${ }^{l} H$ shift $\left(\delta_{H}=7.28\right)$ than alkenes (cyclohexene, $\left.\delta_{H}=5.59\right)$ or cyclically conjugated polyenes such as cyclooctatetraene ( $\delta_{H}=5.69$ ). This is generally explained by the deshielding of the benzene protons by a ring current of $\pi$-electrons ${ }^{2,3}$ which is induced when an aromatic compound is subjected to a magnetic field. The ring current itself produces its own magnetic field, opposing the external field within and above the ring, but aligned with it outside ${ }^{2,3}$. As a result, nuclei inside or above an aromatic ring display a smaller shift whereas nuclei outside the ring on a level with it show a larger shift. The ring current has a stronger effect on the protons attached to or in the ring than on the ring C atoms themselves, so that particularly ${ }^{I} H$ shifts prove a useful means of detecting ring currents and as aromaticity criteria for investigating annulenes.

1,4-Decamethylenebenzene (32) illustrates the ring current of benzene by a shielding of the methylene protons ( $\delta_{H}=0.8$ ) which lie above the aromatic ring plane in the molecule. A clear representation of the ring current effect is given by [18]annulene (33) at low temperature and the vinylogous porphyrin 35 with a diaza[26]annulene perimeter ${ }^{34}$ : the inner protons are strongly shielded ( $\delta_{H}=-2.88$ and -11.64 , respectively); the outer protons are strongly deshielded ( $\delta_{H}=9.25$ and 13.67, respectively). The typical shift of the inner NH protons ( $\delta_{H}=-2$ to -3 ) indicates that porphyrin 34 and its expanded analogues such as $\mathbf{3 5}$ occur as diaza[18]annulene tautomers. Problem 39 draws attention to this point.

33

34

35

### 2.5.3 Intra- and intermolecular hydrogen bonding

Hydrogen bonding can be recognised in ${ }^{I} H$ NMR spectra by the large shifts associated with it ${ }^{2,3}$; these large shifts are caused by the electronegativity of the heteroatoms bridged by the hydrogen atom. The OH protons of enol tautomers of 1,3-diketones are extreme examples. They form an intramolecular $H$ bond and appear between $\delta_{H}=12.5$ (hexafluoroacetylacetone enol, Fig. 2.25) and 15.5 (acetylacetone enol).
Intermolecular $H$ bonding can be recognised in the ${ }^{i} H$ NMR spectrum by the fact that the shifts due to the protons concerned depend very strongly on the concentration, as the simple case of methanol (36) demonstrates (Tig.2.25a), solvalion with teirachloromethane as a solvent breaks down the hydrogen bridging increasingly with dilution of the solution; the OH shift decreases in proportion to this. In contrast, the shift of the ${ }^{I} H$ signal of an intramolecular bridging proton remains almost unaffected if the solution is diluted as illustrated in the example of hexafluoroacetylacetone (37), which is $100 \%$ enolised (Fig. 2.25b).
Intermolecular $H$ bonding involves an exchange of hydrogen between two heteroatoms in two different molecules. The $H$ atom does not remain in the same molecule but is exchanged. If its exchange frequency is greater than is given by the Heisenberg uncertainty principle,

$$
\begin{equation*}
v_{\text {exchange }} \geqq \pi J_{A X} / \sqrt{2}-2.22 J_{A X} \tag{6}
\end{equation*}
$$

then its coupling $J_{A X}$ to a vicinal proton $H^{4}$ is not resolved. Hence $\mathrm{C} H_{n}$ protons do not generally show splitting by vicinal $\mathrm{SH}, \mathrm{OH}$ or NH protons at room temperature. The same holds for ${ }^{3} J_{\mathrm{CH}}$ couplings with such protons. If the hydrogen bonding is hindered by solvatation or is intramolecular, then coupling is resolved, as the example of salicylaldehyde (10) has already shown (see Section 2.2.4; for applications, see problems 17 and 25).

Figure 2.25. 'H NMR spectra of methanol (36, a) and hexafluoroacetylacetone (37, b), both in the pure state (above) and diluted in tetrachloromethane solution ( $5 \%$, below) $\left[25^{\circ} \mathrm{C}, 90 \mathrm{MHz}, \mathrm{CW}\right.$ recording]

### 2.5.4 Protonation effects

If a sample contains groups that can take up or lose a proton, $H^{+}\left(\mathrm{NH}_{2}, \mathrm{COOH}\right)$, then one must expect the pH and the concentration to affect the chemical shift when the experiment is carried out in an acidic or alkaline medium to facilitate dissolution. The pH may affect the chemical shift of more distant, nonpolar groups, as shown by the amino acid alanine (38) in neutral (betaine form 38a) or alkaline solution (anion 38b). The dependence of shift on pH follows the path of titration curves; it is possible to read off the pK value of the equilibrium from the point of inflection ${ }^{2,6}$.

$\mathrm{pH}=6$

$+\left[\mathrm{H}^{\oplus+}\right]$

$\mathrm{pH}=12$

38b
${ }^{13} \mathrm{C}$ shifts respond to pH changes with even greater sensitivity; this is demonstrated by the values of pyridine (39b) and its cation (39a).

39a

The effect of pH is rarely of use for pK measurement; it is more often of use in identifying the site of protonation/deprotonation when several basic or acidic sites are present. Knowing the incremental substitutent effects $Z^{4-6}$ of amino and ammonium groups on benzene ring shifts in aniline and in the anilinium ion (40), one can decide which of the nitrogen atoms is protonated in procaine hydrochloride (problem 24).

### 2.6 Molecular dynamics (fluxionality)

### 2.6.1 Temperature-dependent Ninir spectra

Figure 2.26 shows the ${ }^{1} H$ NMR spectrum of $N, N$-dimethylacetamide (41) and its dependence on temperature. At $55^{\circ} \mathrm{C}$ and below two resonances appear for the two N -methyl groups. Above $55^{\circ} \mathrm{C}$ the signals become increasingly broad until they merge to form one broad signal at $80^{\circ} \mathrm{C}$. This temperature is referred to as the coalescence temperature, $T_{c}$. Above $T_{c}$ the signal, which now belongs to both $N$-methyl groups, becomes increasingly sharp.
The temperaturc-dependent position and profile of the $N$-methyl signal result from amide canonical formulae of $\mathbf{4 1}$ shown in Fig. 2.26: the CN bond is a partial double bond; this hinders rotation of the $N, N$-dimethylamino group. One methyl group is now cis ( $\delta_{B}=3.0$ ) and the other is trans ( $\delta_{A}$ $=2.9)$ to the carboxamide oxygen. At low temperatures $\left(55^{\circ} \mathrm{C}\right)$, the $N$-methyl protons slowly exchange positions in the molecule (slow rotation, slow exchange). If energy is increased by heating (to above $90^{\circ} \mathrm{C}$ ), then the $N, N$-dimethylamino group rotates so that the $N$-methyl protons exchange their position with a high frequency (free rotation, rapid exchange), and one single, sharp $N$-methyl signal of double intensity appears with the average shift $\left(\delta_{B}+\delta_{A}\right) / 2=2.95$.

$\longleftrightarrow$
41

Figure 2.26. ${ }^{1} \mathrm{H}$ NMR spectra of $\mathrm{N}, \mathrm{N}$-dimethylacetamide (41) at the temperatures indicated $\left[\left(\mathrm{CD}_{3}\right)_{2} \mathrm{SO}, 75 \% \mathrm{v} / \mathrm{v}\right.$, $80 \mathrm{MHz}]$

The dimethylamino group rotation follows a first-order rate law; the exchanging methyl protons show no coupling and their singlet signals are of the same intensity. Under these conditions, equation $7^{2,35-37}$ affords the rate constant $k_{r}$ at the coalescence point $T_{c}$ :

$$
\begin{equation*}
k_{r}=\pi\left(v_{A}-v_{B}\right) / \sqrt{2}=\pi \Delta v / \sqrt{2} \cong 2.22 \Delta v \tag{7}
\end{equation*}
$$

where $\Delta v$ is the full width at half-maximum of the signal at the coalesence point $T_{c}$; it corresponds to the difference in chemical shift $\left(v_{B}-v_{A}\right)$ observed during slow exchange. In the case of dimethylacetamide (41) the difference in the chemical shift is 0.1 ppm (Fig. 2.26), i.e. 8 Hz (at 80 MHz ). From equation 7 it can then be calculated that the $N$-methyl groups at the coalescence point ( $80^{\circ} \mathrm{C}$ or 353 K ) rotate with an exchange frequency of $k_{r}=2.22 \times 8=17.8 \mathrm{~Hz}$. According to the Eyring equation 8 , the exchange frequency $k_{r}$ decreases exponentially with the free molar activation energy $\Delta G^{35-37}$ :

$$
\begin{equation*}
k_{r}=\frac{k T_{c}}{h} e^{-\Delta G / R T_{c}} \tag{8}
\end{equation*}
$$

where $R$ is the gas constant, $k$ is the Boltzmann constant and $h$ is the Planck constant. Equations 7 and 8 illustrate the value of temperature-dependent NMR for the investigation of molecular dynamics: following substitution of the fundamental constants, they give equation 9 for the free molar activation energy $\Delta G$ for first-order exchange processes:

$$
\begin{equation*}
\Delta G=19.1 T_{c}\left[10.32+\log \left(T_{c} / k_{r}\right)\right] \times 10^{-3} \mathrm{~kJ} / \mathrm{mol} \tag{9}
\end{equation*}
$$

Hence the activation energy barrier to dimethylamino group rotation in dimethylacetamide (41) is calculated from equation 9 with $k_{r}=17.8 \mathrm{~s}^{-1}$ at the coalescence point 353 K (Fig. 2.26):

$$
\Delta G_{353}=78.5 \mathrm{~kJ} / \mathrm{mol} \text { or } 18.7 \mathrm{kcal} / \mathrm{mol}
$$

Temperature-dependent (dynamic) NMR studies are suited to the study of processes with rate constants between $10^{-1}$ and $10^{3} \mathrm{~s}^{-1}$. Some applications are shown in Table 2.13 and in problems 13 and 14.

Table 2.13. Selected applications of dynamic proton resonance ${ }^{35-37}$

| Rotation hindered by |

### 2.6.2 ${ }^{13} \mathrm{C}$ Spin-lattice relaxation times

The spin-lattice relaxation time $T_{l}$ is the time constant with which an assembly of a particular nuclear spin in a sample becomes magnetised parallel to the magnetic field as it is introduced into it. The sample magnetisation $M_{0}$ is regenerated after every excitation with this time constant. For organic molecules the $T_{l}$ values of even differently bonded protons in solution are of the same order of magnitude ( $0.1-10 \mathrm{~s}$ ). ${ }^{13} \mathrm{C}$ nuclei behave in a way which shows greater differentiation between nuclei and generally take more time: in molecules of varying size and in different chemical environments the spin-lattice relaxation times lic between a few milliscconds (macromolecules) and several minutes (quaternary C atoms in small molecules). With ${ }^{l} H$ broadband decoupling only one $T_{l}$ value is recorded for each C atom (rather than $n T_{l}$ values as for all $n$ components of a complex ${ }^{1} H$ multiplet), and these ${ }^{13} \mathrm{C}$ spin-lattice relaxation times are useful parameters for probing molecular mobility in solution.
The technique for measurement which is most easily interpreted is the inversion-recovery method, in which the distribution of the nuclear spins among the energy levels is inverted by means of a suitable $180^{\circ}$ radiofrequency pulse ${ }^{2-6,17}$. A negative signal is observed at first, which becomes increasingly positive with time (and hence also with increasing spin-lattice relaxation) and which
finally approaches the equilibrium intensity asymptotically. Figures 2.27 and 2.28 show asymptotical increases in the signal amplitude due to ${ }^{13} \mathrm{C}$ spin-lattice relaxation up to the equilibrium value using two instructive examples. A simple analysis makes use of the 'zero intensity interval', $\tau_{0}$, without consideration of standard deviations: after this time interval $\tau_{0}$, the spin-lattice relaxation is precisely far enough advanced for the signal amplitude to pass through zero. Equation 10 then gives $T_{l}$ for each individual C atom.

$$
\begin{equation*}
T_{1}=\tau_{0} / \ln 2 \sim 1.45 \tau_{0} \tag{10}
\end{equation*}
$$

Thus, in the series of $T_{1}$ measurements of 2-octanol (42, Fig. 2.27) for the methyl group at the hydrophobic end of the molecule, the signal intensity passes through zero at $\tau_{0}=3.8 \mathrm{~s}$. From this, using equation 10 , a spin-lattice relaxation time of $T_{I}=5.5 \mathrm{~s}$ can be calculated. A complete relaxation of this methyl C atom requires about five times longer (more than 30 s ) than is shown in the last experiment of the series (Fig. 2.27); $T_{l}$ itself is the time constant for an exponential increase, in other words, after $T_{l}$ the difference between the observed signal intensity and its final value is still $1 / \mathrm{e}$ of the final amplitude.

Figure 2.27. Sequence of measurements to determine the ${ }^{13} \mathrm{C}$ spin-lattice relaxation times of 2-octanol (42) [ $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}, 75 \% \mathrm{v} / \mathrm{v}, 25^{\circ} \mathrm{C}, 20 \mathrm{MHz}$, inversion-recovery sequence, stacked plot]. The times at which the signals pass through zero, $\tau_{0}$, have been used to calculate, by equation 10 , the $T_{1}$ values shown above for the ${ }^{13} \mathrm{C}$ nuclei of 2-octanol

If smaller NOE enhancements are recorded for certain ${ }^{13} \mathrm{C}$ nuclei, then other mechanisms (e.g. spin-rotation) contribute to their spin-lattice relaxation ${ }^{5,6}$.
The main contribution to the spin-lattice relaxation of ${ }^{13} \mathrm{C}$ nuclei which are connected to hydrogen is provided by the dipole-dipole interaction (DD mechanism, dipolar relaxation). For such ${ }^{13} \mathrm{C}$ nuclei a nuclear Overhauser enhancement of almost 2 will be observed during ${ }^{1} H$ broadband decoupling according to:

$$
\begin{equation*}
\eta_{c}=\gamma_{H} / 2 \gamma_{C}=1.988 \tag{11}
\end{equation*}
$$

where $\gamma_{\mathrm{H}}$ and $\gamma_{\mathrm{C}}$ are the gyromagnetic constants of ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$.
Dipolar relaxation of ${ }^{13} \mathrm{C}$ nuclei originates from the protons (larger magnetic moment) in the same or in neighbouring molecules, which move with molecular motion (translation, vibration, rotation). This motion generates fluctuating local magnetic fields which affect the observed nucleus. If the frequency of a local magnetic field matches the Larmor frequency of the ${ }^{13} \mathrm{C}$ nucleus being observed (resonance condition), then this nucleus can undergo transition from the excited state to the ground state (relaxation) or the reverse (excitation). From this, it follows that the spin-lattice relaxation is linked to the mobility of the molecule or molecular fragment. If the average time taken between two reorientations of the molecule or fragment is defined as the effective correlation time $\tau_{c}$, and if $n H$ atoms are connected to the observed C , then the dipolar relaxation time $T_{I(D D)}$ is given by the correlation function:

$$
\begin{equation*}
T_{l(D D)}{ }^{-1}=\text { constant } \times n \tau_{c} \tag{12}
\end{equation*}
$$

Accordingly, the relaxation time of a C atom will increase the fewer hydrogen atoms it bonds to and the faster the motion of the molecule or molecular fragment in which it is located. From this, it can be deduced that the spin-lattice relaxation time of ${ }^{13} \mathrm{C}$ nuclei provides information concerning four molecular characteristics:

- Molecular size: smaller molecules move more quickly than larger ones; as a result, C atoms in small molecules relax more slowly than those in large molecules. The C atoms in the more mobile cyclohexanes ( $T_{l}=19-20 \mathrm{~s}$ ) take longer than those in the more sluggish cyclodecane ( $T_{l}=4-5 \mathrm{~s}$ ) 5,6 .
- The number of bonded $H$ atoms: if all parts within a molecule move at the same rate (the same $\tau_{\mathrm{c}}$ for all C atoms), the relaxation times $T_{l}$ decrease from CH via $\mathrm{CH}_{2}$ to $\mathrm{CH}_{3}$ in the ratio given by:

$$
\begin{equation*}
T_{1}(\mathrm{CH}): T_{1}\left(\mathrm{CH}_{2}\right): T_{1}\left(\mathrm{CH}_{3}\right)=6: 3: 2 \tag{13}
\end{equation*}
$$

Since methyl groups also rotate freely in otherwise rigid molecules, they follow the ratio shown in equation 13 only in the case of considerable steric hindrance ${ }^{6}$. In contrast, the $T_{1}$ values of ${ }^{13} \mathrm{C}$ nuclei of CH and $\mathrm{CH}_{2}$ groups follow the ratio $2: 1$ even in large, rigid molecules. Typical examples are steroids such as cholesteryl chloride (43), in which the $\mathrm{CH}_{2}$ groups of the ring relax at approximately double the rate ( $0.2-0.3 \mathrm{~s}$ ) of $\mathrm{C} H$ carbon atoms $(0.5 \mathrm{~s})$. Contrary to the prediction made by equation 13 , freely rotating methyl groups require considerably longer ( 1.5 s ) for spinlattice relaxation.

- Segmental mobility: if one examines the $T_{l}$ series of 2-octanol (42, Fig. 2.27) calculated according to equation 10 , it becomes apparent that the mobility parameters $n T_{l}$ increase steadily from $\mathrm{C}-2$ to $\mathrm{C}-8$. As a result of hydrogen bonding, the molecule close to the OH groups is almost rigid ( $n T_{l}$ between 3.5 and 4.4 s ). With increasing distance from the anchoring effect of the OH group the mobility increases; the spin-lattice relaxation time becomes correspondingly longer. The $n T_{l}$ values of the two methyl groups also reflect the proximity to ( 7.8 s ) and distance from ( 16.5 s ) the hydrogen bond as a 'braking' device.

Figure 2.28. Sequence of measurements to determine the spin-lattice relaxation times of the ${ }^{13} \mathrm{C}$ nuclei of the pyridine ring in L-nicotine (46) [(CD $\left.\mathrm{D}_{3}\right)_{2} \mathrm{CO}, 75 \% \mathrm{v} / \mathrm{v}, 25^{\circ} \mathrm{C}$, inversion-recovery sequence, 20 MHz . The times at which signals pass through zero have been used to calculate, by equation 10 , the $T_{1}$ values for the pyridine $C$ atoms in L-nicotine

- Anisotropy of molecular motion: monosubstituted benzene rings, e.g. phenyl benzoate (44), show a very typical characteristic: in the para position to the substituents the CH nuclei relax considerably more rapidly than in the ortho and meta positions. The reason for this is the anisotropy
of the molecular motion: the benzene rings rotate more easily around an axis which passes through the substituents and the para position, because this requires them to push aside the least number of neighbouring molecules. This rotation, which affects only the $o$ - and $m-\mathrm{CH}$ units, is too rapid for an effective spin-lattice relaxation of the $o$ - and $m$-C atoms. More efficient with respect to relaxation are the frequencies of molecular rotations perpendicular to the preferred axis, and these affect the CH bond in $p$-position. If the phenyl rotation is impeded by bulky substituents, e.g. in $2,2^{\prime}, 6,6^{\prime}-$ tetramethylbiphenyl (45), then the $T_{l}$ values of the CH atoms can be even less easily distinguished in the meta and para positions ( 3.0 and 2.7 s , respectively). Particularly large spin-lattice relaxation times obtained for non-protonated carbon nuclei of 45 and 46 arise from less efficient, non-dipolar relaxation mechanisms.

44

45

46

Figure 2.28 shows the anisotropy of the rotation of the pyridine ring in nicotine (46). The main axis passes through C-3 and C-6; C-6 relaxes correspondingly more rapidly ( 3.5 s ) than the three other CH atoms ( 5.5 s ) of the pyridine ring in nicotine, as can be seen from the times at which the appropriate signals pass through zero.

### 2.7 Summary

Table 2.14 summarizes the steps by which molecular structures can be determined using the NMR methods discussed thus far to determine the skeleton structure, relative configuration and conformation of a specific compound.
In the case of completely unknown compounds, the molecular formula is a useful source of additional information; it can be determined using small amounts of substance (a few micrograms) by high-resolution mass spectrometric determination of the accurate molecular mass. It provides information concerning the double-bond equivalents (the 'degree of unsaturation' - the number of multiple bonds and rings). For the commonest heteroatoms in organic molecules (nitrogen, oxygen, suiphur, halogen), the number of double-bond equivalents can be derived from the molecular formula by assuming that oxygen and sulphur may be omitted and require no replacement atom, halogen may be replaced by hydrogen and nitrogen may be replaced by $\mathrm{C} H$. The resulting empirical formula $\mathrm{C}_{n} H_{x}$ is then compared with the empirical formula of an alkane with $n \mathrm{C}$ atoms, $\mathrm{C}_{n} H_{2 n+2}$; the number of double-bond equivalents is equal to half the hydrogen deficit,

$$
(2 n+2-x) / 2
$$

From $\mathrm{C}_{8} H_{9} \mathrm{NO}$ (problem 4), for example, the empirical formula $\mathrm{C}_{9} H_{10}$ is derived and compared with the alkane formula $\mathrm{C}_{9} \mathrm{H}_{2}$; a hydrogen deficit of ten and thus of five double-bond equivalents is deduced. If the NMR spectra have too few signals in the shift range appropriate for multiple bonds, then the double-bond equivalents indicate rings (see, for example, $\alpha$-pinene, Fig. 2.4).

If the amount of the sample is sufficient, then the carbon skeleton is best traced out from the twodimensional INADEQUATE experiment. If the absolute configuration of particular C atoms is needed, the empirical applications of diastereotopism and chiral shift reagents are useful (Section 2.4). Anisotropic and ring current effects supply information about conformation and aromaticity (Section 2.5), and pH effects can indicate the site of protonation (problem 24). Temperaturedependent NMR spectra and ${ }^{13} \mathrm{C}$ spin-lattice relaxation times (Section 2.6) provide insight into molecular dynamics (problems 13 and 14).

Table 2.14. Suggested tactics for solving structures using NMR

## 3 PROBLEMS

In the following 55 problems, the chemical shift value (ppm) is given in the scale below the spectra and the coupling constant $(\mathrm{Hz})$ is written immediately above or below the appropriate multiplet. Proton NMR data are italicised throughout in order to distinguish them from the parameters of other nuclei $\left({ }^{13} \mathrm{C},{ }^{15} \mathrm{~N}\right)$.

## Problem 1

${ }^{l} H$ NMR spectrum 1 was obtained from dimethyl cyclopropanedicarboxylate. Is it a cis or a trans isomer?
Conditions: $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 400 \mathrm{MHz}$.

## Problem 2

From which compound of formula $\mathrm{C}_{5} H_{8} \mathrm{O}_{2}$ was ${ }^{\prime} H$ NMR spectrum 2 obtained? Conditions: $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 90 \mathrm{MHz}$.
2

## Problem 3

Which stereoisomer of the compound $\mathrm{C}_{5} \mathrm{H}_{6} \mathrm{O}$ is present given spectrum $\mathbf{3}$ ? Conditions: $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 90 \mathrm{MHz}$.

## Problem 4

Which stereoisomer of the compound $\mathrm{C}_{8} H_{9} \mathrm{NO}$ can be identified from ${ }^{l} H$ NMR spectrum 4 ? Conditions: $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 90 \mathrm{MHz}$.

4

## Problem 5

The reaction of $2,2^{\prime}$-bipyrrole with orthoformic acid triethyl ester in the presence of phosphoryl chloride ( $\mathrm{POCl}_{3}$ ) produced a compound which gave the ${ }^{1} H$ NMR spectrum 5 . Which compound has been prepared?
Conditions: $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 400 \mathrm{MHz}$.
Two broad $\mathrm{D}_{2} \mathrm{O}$-exchangeable signals at $\delta_{H}=11.6$ (one proton) and 12.4 (two protons) are not shown.

## Problem 6

From which compound $\mathrm{C}_{7} H_{7} \mathrm{NO}$ was ${ }^{l} H$ NMR spectrum 6 obtained?
Conditions: $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 90 \mathrm{MHz}$.
6

## Problem 7

From which compound $\mathrm{C}_{16} H_{10} \mathrm{O}_{2}$ was ${ }^{l} H$ NMR spectrum 7 obtained?
Conditions: $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 400 \mathrm{MHz}$.

## Problem 8

One functional group and three substructures given by the ${ }^{I} H$ NMR spectrum 8 make up the molecular structure including the relative configuration of the sample compound.
Conditions: $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 400 \mathrm{MHz}$.
8

## Problem 9

Which substituted isoflavone can be identified from ${ }^{\prime} H$ NMR spectrum 9 ?
Conditions: $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 200 \mathrm{MHz}$.

## Problem 10

A natural substance of elemental composition $\mathrm{C}_{15} \mathrm{H}_{14} \mathrm{O}_{6}$ was isolated from the plant Centaurea chilensis (Compositae). What is the structure and relative configuration of the substance given its ${ }^{I} H$ NMR spectrum 10 with (top) and without (bottom) deuterium exchange $\mathbf{1 0}$ ?
Conditions: $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 400 \mathrm{MHz}$.
10

Problem 10, continued

## Problem 11

Characterisation of the antibiotic monordene (also referred to as radicicol) with the elemental composition $\mathrm{C}_{18} \mathrm{H}_{17} \mathrm{O}_{6} \mathrm{Cl}$ isolated from Monosporium bonorden gave the macrolide structure 1 . The relative configuration of the $H$ atoms on the two conjugated double bonds (6,7-cis, 8,9-trans-) could be deduced from the $60 \mathrm{MHz}{ }^{l} H$ NMR spectrum ${ }^{38}$. The relative configuration of the C atoms 2-5, which encompass the oxirane ring as a partial structure, has yet to be established.
The reference compound methyloxirane gives the ${ }^{I} H$ NMR spectrum 11a shown with expanded multiplets. What information regarding its relative configuration can be deduced from the expanded ${ }^{I} H$ multiplets of monordene displayed in 11b?
Conditions: $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}, 25^{\circ} \mathrm{C}, 200 \mathrm{MHz}$.

## Problem 12

From the $H H$ COSY contour plot $\mathbf{1 2 a}$ it can be established which cycloadduct has been produced from 1-( $N, N$-dimethylamino)-2-methylbuta-1,3-diene and trans- $\beta$-nitrostyrene. The ${ }^{3} J_{H H}$ coupling constant in the one-dimensional ${ }^{\prime} H$ NMR spectrum $\mathbf{1 2 b}$ can be used to deduce the relative configuration of the adduct.
Conditions: $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 400 \mathrm{MHz}$.
12

## Problem 13

${ }^{\prime} H$ NMR spectra 13 were recorded for 3-( $N, N$-dimethylamino) acrolein at the temperatures given. What can be said about the structure of the compound and what thermodynamic data can be derived from these spectra?
Conditions: $\mathrm{CDC1}_{3}, 50 \% \mathrm{v} / \mathrm{v}, 250 \mathrm{MHz}$.

13

## Problem 14

${ }^{13} \mathrm{C}$ NMR spectra 14 were recorded of cis-1,2-dimethylcyclohexane at the temperatures given; the DEPT experiment at 223 K was also recorded in order to distinguish the CH multiplicities ( CH and $\mathrm{CH}_{3}$ positive, $\mathrm{CH}_{2}$ negative). Which assignments of resonances and what thermodynamic data can be deduced from these spectra?
Conditions: $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}, 95 \% \mathrm{v} / \mathrm{v}, 100 \mathrm{MHz},{ }^{\prime} \mathrm{H}$ broadband decoupled.
14

## Problem 15

No further information is required to identify this compound from its ${ }^{13} \mathrm{C}$ NMR spectra 15 . Conditions: $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 20 \mathrm{MHz}$. (a) Proton broadband decoupled spectrum; (b) NOE enhanced coupled spectrum (gated decoupling); (c) expanded section of (b).

## Problem 16

In hexadeuteriodimethyl sulphoxide the compound which is labelled as 3-methyl-pyrazolone gives ${ }^{13} \mathrm{C}$ NMR spectra 16. In what form is this compound present in this solution?

Conditions: $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{SO}, 25^{\circ} \mathrm{C}, 20 \mathrm{MHz}$. (a) ${ }^{l} H$ broadband decoupled spectrum; (b) NOE enhanced coupled spectrum (gated decoupling); (c) expanded scetions of (b).

## 16

## Problem 17

The compound $\mathrm{C}_{8} \mathrm{H}_{8} \mathrm{O}_{2}$ gave the ${ }^{13} \mathrm{C}$ NMR spectra 17 . What is its structure?
Conditions: $\mathrm{CDCl}_{3}:\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}(1: 1), 25^{\circ} \mathrm{C}, 20 \mathrm{MHz}$. (a) ${ }^{\prime} \mathrm{H}$ broadband decoupled spectrum;
(b) NOE enhanced coupled spectrum (gated decoupling); (c) expanded section of (b), $\delta_{\mathrm{C}}=118.2$ 136.5.

## Problem 18

1,3,5-Trinitrobenzene reacts with dry acetone in the presence of potassium methoxide to give a crystalline violet compound $\mathrm{C}_{9} H_{8} \mathrm{~N}_{3} \mathrm{O}_{7} \mathrm{~K}$. Deduce its identity from the ${ }^{13} \mathrm{C}$ NMR spectra 18 .
Conditions: $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{SO}, 25^{\circ} \mathrm{C}, 22.63 \mathrm{MIIz}$. (a) ${ }^{l} H$ broadband decoupled spectrum; (b) without dccoupling; (c) expanded section of (b).

## 18

## Problem 19

3-[4-( $N, N$-Dimethylamino)phenyl]-2-ethylpropenal (3) was produced by reaction of $\mathrm{N}, \mathrm{N}$-dimethylaniline (1) with 2-ethyl-3-ethoxyacrolein (2) in the presence of phosphorus oxytrichloride.

Since the olefinic CC double bond is trisubstituted, the relative configuration cannot be determined on the basis of the cis and trans couplings of vicinal alkene protons in the ${ }^{\prime} H$ NMR spectrum. What is the relative configuration given the ${ }^{13} \mathrm{C}$ NMR spectra 19 ?
Conditions: $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 20 \mathrm{MHz}$. (a) ${ }^{1} H$ broadband decoupled spectrum; (b) expanded sp ${ }^{3}$ shift range; (c) expanded $\mathrm{sp}^{2}$ shift range; (b) and (c) each with the ${ }^{l} I I$ broadband decoupled spectrum below and NOE enhanced coupled spectrum above.

## Problem 20

2-Trimethylsilyloxy- $\beta$-nitrostyrene was the target of Knoevenagel condensation of 2-trimethylsiloxybenzaldehyde with nitromethane in the presence of $n$-butylamine as base. ${ }^{13} \mathrm{C}$ NMR spectra 20 were obtained from the product of the reaction. What has happened?
Conditions: $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 20 \mathrm{MHz}$. (a) $\mathrm{sp}^{3}$ shift range; (b) $\mathrm{sp}^{2}$ shift range, in each case with the
${ }^{1} H$ broadband decoupled spectrum below and the NOE enhanced coupled spectrum (gated decoupling).

## 20

## Problem 21

From which compound were the INADEQUATE contour plot and ${ }^{13} \mathrm{C}$ NMR spectra 21 obtained? Conditions: $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}, 95 \% \mathrm{v} / \mathrm{v}, 25^{\circ} \mathrm{C}, 100 \mathrm{MHz}$. (a) Symmetrised INADEQUATE contour plot with ${ }^{13} \mathrm{C}$ NMR spectra; (b) ${ }^{1} H$ broadband decoupled spectrum; (c) NOE enhanced coupled spectrum (gated decoupling); (d) expansion of multiplets of (c).

## Problem 22

The hydrolysis of 3-ethoxy-4-ethylbicyclo[4.1.0]hept-4-en-7-one propylene acetal (1) with aqueous acetic acid in tetrahydrofuran gives an oil with the molecular formula $\mathrm{C}_{12} \mathrm{H}_{18} \mathrm{O}_{3}$, from which the INADEQUATE contour plot $\mathbf{2 2}$ and DEPT spectra were obtained. What is the compound?

Conditions: $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}, 95 \% \mathrm{v} / \mathrm{v}, 25^{\circ} \mathrm{C}, 100 \mathrm{MHz}$. (a) Symmetrised INADEQUATE contour plot; (b-d) ${ }^{13} \mathrm{C}$ NMR spectra, (b) ${ }^{1} H$ broadband decoupled spectrum, (c) DEPT CH subspectrum, (d) DEPT subspectrum, CH and $\mathrm{CH}_{3}$ positive and $\mathrm{CH}_{2}$ negative.

## Problem 23

From which compound $\mathrm{C}_{6} H_{10} \mathrm{O}$ were the NMR spectra 23 recorded?
Conditions: $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}, 25^{\circ} \mathrm{C}, 200 \mathrm{MHz}\left({ }^{1} \mathrm{H}\right), 50 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right)$. (a) ${ }^{I} H$ NMR spectrum with expanded sections; (b,c) ${ }^{13} \mathrm{C}$ NMR partial spectra, each with proton broadband decoupled spectrum below and NOE enhanced coupled spectrum above with expanded multiplets at $\delta_{C}=76.6$ and 83.0.

23

## Problem 24

Procaine hydrochloride gives the ${ }^{1} H$ and ${ }^{13} \mathrm{C}$ NMR spectra 24 . Which amino group is protonated? Conditions: $\mathrm{CDCl}_{3}:\left(\mathrm{CD}_{3}\right)_{2} \mathrm{SO}(3: 1), 25^{\circ} \mathrm{C}, 20 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right), 200 \mathrm{MHz}\left({ }^{1} H\right)$. (a) ${ }^{I} H \mathrm{NMR}$ spectrum with expanded multiplets; (b-d) ${ }^{13} \mathrm{C}$ NMR spectra; (b) ${ }^{1} \mathrm{H}$ broadband decoupled spectrum; (c) NOE enhanced coupled spectrum (gated decoupling); (d) expansion of multiplets ( $\delta_{\mathrm{C}}=113.1-153.7$ ).
24

## Problem 25

Using which compound $\mathrm{C}_{10} H_{10} \mathrm{O}_{4}$ were the NMR spectra 25 recorded?
Conditions: $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}, 25^{\circ} \mathrm{C}, 400 \mathrm{MHz}\left({ }^{l} \mathrm{H}\right), 100 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right)$. (a) ${ }^{l} H$ NMR spectrum with expanded sections; (b,c) ${ }^{13} \mathrm{C}$ NMR spectra, (b) proton broadband decoupled, (c) NOE enhanced coupled spectrum with expanded sections.

## Problem 26

An alkaloid of elemental composition $\mathrm{C}_{11} H_{I I} \mathrm{NO}_{3}$ was isolated from the plant Dactylicapnos torulosa (Fumariaceae). What is the structure of it given its NMR spectra 26?
Conditions: $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 400 \mathrm{MIIz}\left({ }^{1} \mathrm{H}\right), 100 \mathrm{MIIz}\left({ }^{13} \mathrm{C}\right)$. (a) ${ }^{1} H$ NMR spectrum with expanded section; (b,c) ${ }^{13} \mathrm{C}$ NMR spectra, proton broadband decoupled (bottom) and NOE enhanced coupled with expanded sections (top), (b) from $\delta_{\mathrm{C}}=27.6-47.8$, (c) from $\delta_{\mathrm{C}}=101.3$-164.2.

## 26

## Problem 27

3,4-Dihydro- 2 H -pyran-5-carbaldehyde ( $I$ ) was treated with sarcosine ethylester (2) in the presence of sodium ethoxide. What is the structure of the crystalline product $\mathrm{C}_{11} \mathrm{H}_{16} \mathrm{NO}_{3}$ given its NMR spectra 27 ?

Conditions: $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 100 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right), 400 \mathrm{MHz}\left({ }^{l} H\right)$. (a) ${ }^{l} \mathrm{H}$ NMR spectrum with expanded multiplets; (b-e) ${ }^{13} \mathrm{C}$ NMR partial spectra; (b) $\mathrm{sp}^{3}$ shift range; (c) $\mathrm{sp}^{2}$ shift range, each with ${ }^{l} H$ broadband decoupled spectrum (bottom) and the NOE enhanced coupled spectrum (gated decoupling, top) with expansions of multiplets $(\mathbf{d})\left(\delta_{C}=59.5-61.7\right)$ and $(\mathbf{e})\left(\delta_{C}=117.0-127.5\right)$.

## Problem 28

1-Ethoxy-2-propylbuta-1,3-diene and p-toly1 sulphonyl cyanide react to give a crystalline product. What is this product given its NMR spectra set 28 ?
Conditions: $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 100 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right), 400 \mathrm{MHz}\left({ }^{1} H\right)$. (a-e) ${ }^{13} \mathrm{C}$ NMR spcctra; (a,b) ${ }^{1} H$ broadband decoupled spectra; (c,d) NOE enhanced coupled spectra (gated decoupling) with expansion (e) of the multiplets in the $\mathrm{sp}^{2}$ shift range; (f) ${ }^{1} H$ NMR spectrum with expanded multiplets.

## Problem 29

Which compound of formula $\mathrm{C}_{11} H_{12} \mathrm{O}_{2}$ gives the NMR spectra set 29 ?
Conditions: $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 200 \mathrm{MHz}\left({ }^{l} \mathrm{H}\right), 50 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right)$. (a) ${ }^{l} \mathrm{H}$ NMR spectrum with expansion (b) and NOE difference spectra (c,d), with decoupling at $\delta_{H}=2.56(\mathbf{c})$ and $2.87(\mathrm{~d}) ;(\mathrm{e}-\mathrm{g}){ }^{13} \mathrm{C}$ NMR spectra; (e) ${ }^{I} H$ broadband decoupled spectrum; (f) NOE enhanced coupled spectrum (gated decoupling) with expansions (g) ( $\delta_{\mathrm{C}}=23.6,113.3,113.8,127.0,147.8,164.6$ and 197.8); (h, next page) section of the CH COSY diagram.

## Problem 29, continued

 29h

## Problem 30

5-Amino-1,2,4-triazole undergocs a cyclocondensation with 3-ethoxyacrolein (1) to form 1,2,4-triazolo[1,5-a]pyrimidine (3) or its [4,3-a] isomer (5), according to whether it reacts as 1 H or 4 H tautomer 2 or 4 . Moreover, the pyrimidines 3 and 5 can interconvert by a Dimroth rearrangement. Since the ${ }^{1} H$ NMR spectrum $\mathbf{3 0 a}$ does not enable a clear distinction to be made ( $A M X$ systems for the pyrimidinc protons in both isomers), the ${ }^{13} \mathrm{C}$ and ${ }^{15} \mathrm{~N}$ NMR spectra 30b-d were obtained. What is the compound?

30a

## Problem 30, continued

Conditions: $\mathrm{CDCl}_{3}(\mathbf{a}-\mathbf{c}),\left(\mathrm{CD}_{3}\right)_{2} \mathrm{SO}(\mathbf{d}), 25^{\circ} \mathrm{C}, 200 \mathrm{MHz}\left({ }^{1} H\right), 20 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right), 40.55 \mathrm{MHz}\left({ }^{15} \mathrm{~N}\right)$. (a) ${ }^{1} H$ NMR spectrum; (b,c) ${ }^{13} \mathrm{C}$ NMR spectra; (b) ${ }^{1} H$ broadband decoupled spectrum; (c) NOE enhanced coupled spectrum (gated decoupling); (d) ${ }^{15} \mathrm{~N}$ NMR spectrum, without decoupling, with expanded multiplets, ${ }^{15} \mathrm{~N}$ shifts calibrated relative to ammonia as reference ${ }^{7,8}$.

## Problem 31

NMR spectra 31 were obtained from 6-butyltetrazolo[1,5-a]pyrimidine (1). What form does the heterocycle take?

Conditions: $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}, 25^{\circ} \mathrm{C}, 400 \mathrm{MHz}\left({ }^{1} \mathrm{H}\right), 100 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right), 40.55 \mathrm{MHz}\left({ }^{15} \mathrm{~N}\right) .(\text { a })^{l} H \mathrm{NMR}$ spectrum with expanded partial spectra and integrals; (b, c) ${ }^{13} \mathrm{C}$ NMR spectra, in each case showing proton broadband decoupled spectrum below and gated decoupled spectrum above, (b) aliphatic resonances and (c) heteroaromatic resonances; (d) ${ }^{15} \mathrm{~N}$ NMR spectrum, coupled, with expanded sections and integrals.

## 31a

Problem 31, continued

d

## Problem 32

Phthalaldehydic acid (o-formylbenzoic acid) gives the NMR spectra set 32. In what form does the compound actually exist?
Conditions: $\mathrm{CDCl}_{3}:\left(\mathrm{CD}_{3}\right)_{2} \mathrm{SO}(9: 1), 25^{\circ} \mathrm{C}, 80$ and $400 \mathrm{MHz}\left({ }^{1} H\right), 20$ and $100 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right)$. (a) ${ }^{I} I I$ NMR spectrum with expanded section (b) before and after $\mathrm{D}_{2} \mathrm{O}$ exchange; (c,d) ${ }^{13} \mathrm{C}$ NMR spectra; (c) ${ }^{l} H$ broadband decoupled spectrum; (d) NOE enhanced coupled spectrum (gated decoupling);
(e) CH COSY diagram ( $100 / 400 \mathrm{MHz}$ ); (f) HH COSY diagram ( 400 MHz ). The ordinate scales in (e) and (f) are the same.

## 32

## Problem 32, continued

32

## Problem 33

Commercial cyclopentadiene produces the set of NMR spectra 33. In what form does this compound actually exist, and what is its relative configuration?

33a

## Problem 33, continued

Conditions: $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}, 95 \% \mathrm{v} / \mathrm{v}, 25^{\circ} \mathrm{C}, 400$ and $200 \mathrm{MHz}\left({ }^{l} \mathrm{H}\right), 100 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right) .\left(\right.$ a ${ }^{l}{ }^{l} H$ NMR spec$\operatorname{tra}(200 \mathrm{MHz})$ with expansion (above) and $H H$ COSY diagram (below); (b) NOE difference spec$\operatorname{tra}(200 \mathrm{MHz})$ with decoupling at $\delta_{H}=1.25$ and 1.47 ; ( $\left.\mathbf{c}, \mathbf{d}\right) \mathrm{CH}$ COSY contour plots with DEPT subspectra to distinguish CH (positive) and $\mathrm{CH}_{2}$ (negative); (c) alkyl shift range; (d) alkenyl shift range.

## Problem 34

Several shifts and coupling constants in the NMR spectra set 34 are so typical that the carbon skeleton can be deduced without any additional information. An NOE difference spectrum gives the relative configuration of the compound.

## 34

## Problem 34, continued

Conditions: $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 200 \mathrm{MHz}\left({ }^{1} I I\right), 50 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right)$. (a) ${ }^{1} H$ NMR spcctrum with expanded multiplets; (b) NOE difference spectrum, irradiated at $\delta_{H}=1.87$; (c) ${ }^{13} \mathrm{C}$ NMR partial spectra, each with ${ }^{1} H$ broadband decoupled spectrum below and NOE enhanced coupled spectrum (gated decoupling) above; (d) CH COSY diagram ('empty' shift ranges omitted).

## Problem 35

Which CH skeleton can be deduced from the NMR experiments $\mathbf{3 5}$ ? What relative configuration does the ${ }^{1} H$ NMR spectrum indicate?
Conditions: $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}, 90 \% \mathrm{v} / \mathrm{v}, 25^{\circ} \mathrm{C}, 400 \mathrm{MHz}\left({ }^{1} \mathrm{H}\right), 50$ and $100 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right)$. (a) Symmetrised INADEQUATE diagram ( 50 MHz ); (b) CH COSY diagram with expansion (c) of the ${ }^{l} H$ NMR spectrum between $\delta_{I I}=1.5$ and 2.3.

## 35a

Problem 35, continued
35

## Problem 36

No further information is required to identify this compound and its relative configuration from the set of NMR experiments $\mathbf{3 6}$ ?
Conditions: $\left(\mathrm{CDCl}_{3}, 50 \% \mathrm{v} / \mathrm{v}, 25{ }^{\circ} \mathrm{C}, 400 \mathrm{MHz}\left({ }^{I} \mathrm{H}\right), 100 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right)\right.$. (a) Symmetrised INADEQUATE diagram ( 100 MHz ) with ${ }^{\prime} H$ broadband decoupled ${ }^{13} \mathrm{C}$ NMR spectrum (b) and DEPT subspectra (c); (d) CH COSY diagram; (e) ${ }^{I} H$ NMR spectra and NOE difference experiments with decoupling at $\delta_{H}=0.74$ and 3.43.
36

## Problem 37

Cyclohexene oxide and metallated 2-methylpyridine reacted to afford a product which gave the NMR results 37 . Identify the relative configuration of the product and assign the resonances.

## 37

## Problem 37, continued

Conditions: $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 400 \mathrm{MHz}\left({ }^{1} H\right), 100 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right) .(\mathbf{a}, \mathbf{b}){ }^{1} H \mathrm{NMR}$ spectra, aromatic region (a), aliphatic region (b); (c) $H H$ COSY plot of aliphatic shift range; (d) CH COSY plot with DEPT subspectra to distinguish CH and $\mathrm{CH}_{2}$;

## Problem 37, continued

37

## Problem 38

A fragrant substance found in cucumber and melon produces the NMR spectra set 38. The identity and structure of the substance can be derived from these spectra without any further information. Conditions: $\mathrm{CDCl}_{3}, 30 \mathrm{mg}$ per $0.3 \mathrm{ml}, 25^{\circ} \mathrm{C}, 400 \mathrm{MHz}\left({ }^{1} H\right), 100 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right)$.
(a) HH COSY diagram;

## Problem 38, continued

(b) ${ }^{l} H$ NMR spectrum with cxpanded multiplets; (c) ${ }^{13} \mathrm{C}$ NMR partial spectra, each with ${ }^{l} H$ broadband decoupled spectrum below and NOE enhanced coupled spectrum (gated decoupling) above;

## Problem 38, continued

(d) CH COSY diagram with expanded section $\left(\delta_{\mathrm{C}}=133.2-133.3\right)$.

## Problem 39

2,5-Bis(3,4-diethyl-2-pyrrolylmethyl)-3,4-diethyl-1H-pyrrole (2), prepared in situ from the di-tbutylester of the $5,5^{\prime}$-dicarboxylic acid (1), reacts with 4 H -1,2,4-triazole-3,5-dialdehyde (3) in dichloromethane in the presence of trifluoroacetic acid and 2,3 -dichloro- 5,6 -dicyano- $p$-benzoquinone as an oxidation reagent. Dark blue crystals are obtained after chromatographic purification. The dark violet chloroform solution fluoresces purple at 360 nm and gives the NMR experiments $\mathbf{3 9}$. Which compound and which tautomer of it has been formed?
39a

$10.45 \quad 9.39$

## Problem 39, continued

Conditions: $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 500 \mathrm{MHz}\left({ }^{l} H\right), 125 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right)$. (a) ${ }^{l} H$ NMR spectrum and $H H \mathrm{COSY}$ plot of ethyl groups; (b) HC HSQC plot with inserted zoomed section of ethyl groups;

## Problem 39, continued

(c) relevant sections of the $H \mathrm{C}$ HMBC plot.

39c

## Problem 40

What compound $\mathrm{C}_{18} \mathrm{H}_{20} \mathrm{O}_{6}$ can be identified from the CH correlation experiments 40 and the ${ }^{l} \mathrm{H}$ NMR spectra shown above?
Conditions: $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{SO}, 25^{\circ} \mathrm{C}, 200 \mathrm{MHz}\left({ }^{1} \mathrm{H}\right), 50 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right)$. $\mathrm{C} H$ COSY (shaded contours) and CH COLOC plot (unshaded contours) in one diagram; in the ${ }^{1} H$ NMR spectrum the signal at $\delta_{H}=$ 12.34 disappears following $\mathrm{D}_{2} \mathrm{O}$ exchange.

## Problem 41

What compound $\mathrm{C}_{19} \mathrm{H}_{18} \mathrm{O}_{6}$ can be identified from the CH COSY and CH COLOC plots a with the ${ }^{1} H$ NMR spectra shown above and from the ${ }^{13} \mathrm{C}$ NMR spectra $\mathbf{b}$ ?

41a

## Problem 41, continued

Conditions: $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{SO}, 25^{\circ} \mathrm{C}, 200 \mathrm{MHz}\left({ }^{l} \mathrm{H}\right), 50 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right)$.
(a) CH COSY diagram (shaded contours) and CH COLOC spectra (unshaded contours) in one diagram with an expansion of the ${ }^{1} H$ NMR spectrum; (b) parts of ${ }^{13} \mathrm{C}$ NMR spectra to be assigned, with ${ }^{l} H$ broadband decoupled spectrum below and NOE enhanced coupled spectrum (gated decoupling) above.

## Problem 42

3',4',6,7-Tetramethoxyisoflavone (3) was the target of the cyclisation reaction of 3,4-dimethoxyphenol (1) with formyl-(3,4-dimethoxyphenyl)acetic acid (2) in the presence of polyphosphoric acid.

A pale yellow, crystalline product is obtained which fluoresces intense blue and gives the NMR results $\mathbf{4 2}$. Does the product have the desired structure?

Conditions: $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 200 \mathrm{MHz}\left({ }^{l} \mathrm{H}\right), 50 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right)$. (a) CH COSY (shaded contours) and CH COLOC diagrams (unshaded contours) in one diagram with enlarged section (b), and with expanded methoxy quartets (c); (d) sections of ${ }^{13} \mathrm{C}$ NMR spectra, each with ${ }^{1} H$ broadband decoupled spectrum below and NOE enhanced coupled spectrum (gated decoupling) above.

## 42d

Problem 42, continued

## Problem 43

An aflatoxin is isolated from Aspergillus flavus. Which of the three aflatoxins, $\mathrm{B}_{1}, \mathrm{G}_{1}$ or $\mathrm{M}_{1}$, is it given the set of NMR experiments 43 ?

Conditions: $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{SO}, 25{ }^{\circ} \mathrm{C}, 200 \mathrm{MHz}\left({ }^{l} H\right), 50 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right)$. (a) Sections of ${ }^{13} \mathrm{C}$ NMR spectra, in each case with ${ }^{1} H$ broadband decoupled spectrum below and NOE enhanced spectrum (gated decoupling) above;

43a

## Problem 43, continued

(b) CH COSY (shaded contours) and CH COLOC plots (unshadcd contours) in onc diagram with expanded ${ }^{l} H$ multiplets.

## Problem 44

The degradation of 2,6-xylenol (2,6-dimethylphenol) by bacteria produces a metabolite with elemental composition $\mathrm{C}_{8} H_{10} \mathrm{O}_{2}$ as determined by high-resolution mass spectrometry ${ }^{39}$. Which carbon skeleton and which relative configuration are deducible from the NMR experiments 44, all obtained from one 1.5 mg sample?
Conditions: $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, 400 \mathrm{MHz}\left({ }^{1} H\right), 100 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right)$. (a) $H H$ COSY plot with ${ }^{1} H$ NMR spectrum and $H H$ coupling constants; the signal at $\delta_{H}=2.17$ belongs to acetone (impurity).

## 4 SOLUTIONS TO PROBLEMS

## 1 Dimethyl cis-cyclopropane-1,2-dicarboxylate

In the ${ }^{l} H$ NMR spectrum it is possible to discern a four-spin system of the $A M X_{2}$ type for the three different kinds of proton of the cis-1,2-disubstituted cyclopropane ring. The $X_{2}$ protons form a doublet of doublets with cis coupling ${ }^{3} J_{A X}(8.5 \mathrm{~Hz})$ and trans coupling ${ }^{3} J_{M X}(6.7 \mathrm{~Hz})$. The signals of protons $H^{A}$ and $H^{M}$ also show geminal coupling ${ }^{2} J_{A M}(5.1 \mathrm{~Hz})$ and splitting into triplets (two $H^{K}$ ) of doublets. The trans isomer would show a four-spin system of the type $A A^{\prime} B B^{\prime}$ or $A A^{\prime} X X^{\prime}$ (according to the shift difference relative to the coupling constant) for the ring protons.

Multiplicities and coupling constants (Hz)

$3 J_{\Delta X}=8.5$ (cis)
$3^{3} J_{M X}=6.7$ (trans)
$2 J_{A M}=5.1$ (geminal)

## 2 Ethylacrylate

The empirical formula implies two double-bond equivalents. The ${ }^{l} H$ NMR spectrum shows multiplet systems whose integral levels are consistent with the eight $H$ atoms of the empirical formula in a ratio of $3: 2: 3$. The triplet at $\delta_{H}=1.3$ and the quartet at $\delta_{H}=4.2$ with the common coupling constant of 7 Hz belong to the $A_{3} X_{2}$ system of an ethoxy group, $-\mathrm{OCH}_{2} \mathrm{CH}_{3}$. Three alkene protons between $\delta_{H}=5.7$ and 6.6 with the trans, cis and geminal couplings ( 13,8 and 2 Hz ) which are repeated in their coupling partncrs, identify the $A D C$ system of a vinyl group, $-\mathrm{CH}=\mathrm{CH}_{2}$. If one combines both structural elements $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{O}+\mathrm{C}_{2} \mathrm{H}_{3}=\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}\right)$ and compares the result with the empirical formula ( $\mathrm{C}_{5} \mathrm{H}_{8} \mathrm{O}_{2}$ ), then C and O as missing atoms give a CO double hond in accordance with the second double-bond equivalent. Linking the structural elements together leads to ethyl acrylate.
${ }^{1} \mathrm{H}$ chemical shifts $\delta_{H}$

Multiplicities and coupling constants ( Hz )

Note how dramatically the roofing effects of the $A B$ and $B C$ part systems change the intensities of the doublet of doublets of proton $B$ in spectrum 2.

## 3 cis-1-Methoxybut-1-en-3-yne

Three double-bond equivalents which follow from the empirical formula can be confirmed in the ${ }^{l} H$ NMR spectrum using typical shifts and coupling constants. The proton signal at $\delta_{H}=3.05$ indicates an ethynyl group with terminal proton $H^{A}$; an $M X$ system in the alkene shift range with $\delta_{M}=4.50$ and $\delta_{X}=6.30$, respectively, and the coupling constants ${ }^{3} J_{M X}=8 \mathrm{~Hz}$, reveal an ethene unit $(-\mathrm{CH}=\mathrm{CH}-)$ with a cis configuration of the protons. The intense singlet at $\delta_{H}=3.8$ belongs to a methoxy group, $-\mathrm{OCH}_{3}$, whose $-I$ effect deshields the $H^{X}$ proton, whilst its $+M$ effect shields the $H^{M}$ proton. The bonding between the ethenyl and ethynyl groups is reflected in the long-range couplings ${ }^{4} J_{A M}=3$ and ${ }^{5} J_{A X}=1 \mathrm{~Hz}$.

## 4 trans-3-(N-Methylpyrrol-2-yl)propenal

The empirical formula contains five double-bond equivalents. In the ${ }^{l} H$ NMR spectrum a doublet signal at $\delta_{H}=9.55$ stands out. This chemical shift value would fit an aldehyde function. Since the only oxygen atom in the empirical formula is thus assigned a place, the methyl signal at $\delta_{H}=3.80$ does not belong to a methoxy group, but rather to an $N$-methyl group.
The coupling constant of the aldehyde doublet ( 7.8 Hz ) is repeated in the doublet of doublets signal at $\delta_{H}=6.3$. Its larger splitting of 15.6 Hz is observed also in the doublet at $\delta_{H}=7.3$ and indicates a CC double bond with a trans configuration of the vicinal protons.
The coupling of 7.8 Hz in the signals at $\delta_{H}=9.55$ and 6.3 identifies the $(E)$-propenal part structure. The large ${ }^{l} H$ shift $\left(\delta_{H}=9.55\right)$ thus reflects the $-M$ effect of the conjugated carbonyl group.

Apart from the $N$-methyl group, three double-bond equivalents and three multiplets remain in the chemical shift range appropriate for electron rich heteroaromatics, $\delta_{H}=6.2$ to 6.9 . $N$-Methylpyrrole is such a compound. Since in the multiplets at $\mathcal{S}_{H}=6.25$ and 6.80 the ${ }^{3} J_{H H}$ coupling of 4.0 Hz is appropriate for pyrrole protons in the 3 - and 4 -positions, the pyrrole ring is deduced to be substituted in the 2-position.

## 5 1,9-Bis(pyrrol-2-yl)pyrromethene

The multiplets are sorted according to identical coupling constants which identify coupling partners, and after comparing $J$-values with characteristic pyrrole ${ }^{3} J_{H H}$ couplings, two structural fragments A and B are deduced. The $A B X$ system $\left({ }^{3} J_{A B}=4.4,{ }^{4} J_{A X}=2.2\right.$ and ${ }^{4} J_{B X}=2.6 \mathrm{~Hz}$ for $\left.X=\mathrm{N} H\right)$ with $\delta_{H}=6.73\left(H^{A}\right)$ and $\delta_{H}=7.00\left(H^{B}\right)$ belongs to the 2,5 -disubstituted pyrrole ring $\mathbf{A}$. The remaining three multiplets at $\delta_{H}=6.35,6.89$ and 7.17 form an $A B C$ system, in which each of the vicinal couplings of the pyrrole ring ( ${ }^{3} J_{A B}=3.7$ and ${ }^{3} J_{A C}=2.5 \mathrm{~Hz}$ ) characterises a 2-monosubstituted pyrrole ring B.

Each of the two pyrrole rings occurs twice in the molecule judging by their inlegrated intensities relative to the methine singlet at $\delta_{H}=6.80$. Their connection with the methine group, which itself only occurs once ( $\delta_{H}=6.80$ ), gives $1,9-$ bis(pyrrol-2-yl)pyrromethene $\mathbf{C}$, a result which is illuminating in view of the reaction which has been carried out. An NOE between the protons at $\delta_{H}=$ 6.80 and 6.73 (not shown) confirmed the cis configuration of the central double bond as drawn. The symmetry is produced by exchange of the NH proton in the rings $\mathbf{A}$.

## 6 3-Acetylpyridine

The ${ }^{\prime} H$ NMR spectrum contains five signals with integral levels in the ratios $1: 1: 1: 1: 3$; four lie in the shift range appropriate for aromatics or heteroaromatics and the fifth is evidently a methyl group. The large shift values (up to $\delta_{H}=9.18$, aromatics) and typical coupling constants ( 8 and 5 Hz ) indicate a pyridine ring, which accounts for four out of the total five double-bond equivalents.
Four multiplets between $\delta_{H}=7.46$ and 9.18 indicate monosubstitution of the pyridine ring, either in the 2- or 3-position but not in the 4-position, since for a 4 -substituted pyridine ring an $A A^{\prime} X X^{\prime}$ system would occur. The position of the substituents follows from the coupling constants of the threefold doublet at $\delta_{H}=7.46$, whose shift is appropriate for a $\beta$-proton on the pyridine ring (A).

The 8 Hz coupling indicates a proton in the $\gamma$-position (B); the 5 Hz coupling locates a vicinal proton in position $\alpha(\mathbf{C})$, the additional 0.9 Hz coupling locates the remaining proton in position $\alpha^{\prime}$ (D) and thereby the $\beta$-position of the substituent.

A

B

C

D

This example shows how it is possible to pin-point the position of a substituent from the coupling constant of a clearly structured multiplet, whose shift can be established beyond doubt. The coupling constants are repeated in the multiplets of the coupling partners; from there the assignment of the remaining signals follows without difficulty. A monosubstituted pyridine ring and a methyl group add up to $\mathrm{C}_{6} H_{7} \mathrm{~N}$. The atoms C and O which are missing from the empirical formula and one additional double-bond equivalent indicate a carbonyl group. The only structure compatible with the presence of these fragments is 3-acctylpyridine.

Multiplicities and coupling constants ( Hz )

## 7 Anthracene-1,8-dialdehyde

The ${ }^{l} H$ NMR spectrum displays six signals with integral levels in the ratios $1: 2: 1: 2: 2: 2$ in accordance with ten protons present in the empirical formula. All chemical shifts indicate protons attached to trigonal carbons. Three of those belong to benzenoid protons which are deshielded hy electron withdrawing substituents $\left(\delta_{A}=7.80 \mathrm{dd}, \delta_{M}=8.28\right.$ and $\left.\delta_{X}=8.44\right)$. The doublet of doublets at $\delta_{H}=7.80$ displays two ortho couplings ( 8.5 and 7.0 Hz ) so that the three-spin system $(A M X)$ reveals a $1,2,3$-trisubstituted benzenoid ring A. The electron withdrawing substituent turns out to be the aldehyde group $\mathbf{B}$ according to the chemical shift ( $\delta_{H}=10.40$ ). Partial structures $\mathbf{A}$ and $\mathbf{B}$ occur twice in the molecule on the basis of the integral levels of their proton signals in spectrum 7 giving rise to the partial formula $\mathrm{C}_{14} \mathrm{H}_{8} \mathrm{O}_{2}$ which already includes both oxygen atoms, so that no phenolic OH is present. Thus, the remaining two singlet signals belong to two methinc fragments $\mathbf{C}$ and $\mathbf{D}$, each one representing formally one half of a double bond. Both complete the molecular formula $\mathrm{C}_{16} H_{10} \mathrm{O}_{2}$. One of the methine protons is extremely deshielded ( $\delta_{H}=11.05$ ).

D
The substructures A-D account for eleven of the total of twelve double bond equivalents so that the compound contains one additional ring as present in anthracene or phenanthrene skeletons.

From all symmetrically substituted anthracene and phenanthrene dialdehydes $\mathbf{E}-\mathbf{H}$ containing 1,2,3-trisubstituted benzene rings,

E

F

G

H
only anthracene-1,8-dialdehyde $\mathbf{E}$ explains six proton signals (not five as cxpected for regioisomers $\mathbf{F - H}$ ) in the ${ }^{l} H$ NMR spectrum 7 as well as the outstanding deshielding of the methine proton ( $\delta_{H}=11.05$ ) attached to C-9 arising from accumulated anisotropic and mesomeric effects of two adjacent aldehyde groups.

Multiplicities and coupling constants ( Hz )

## 8 trans-Stilbene-4-aldehyde

The singlet signal at $\mathcal{S}_{H}=10.0$ indicates an aldehyde function $\mathbf{A}$. An $A B$ two-spin system ( $\mathcal{\delta}_{A}=$ 7.16 and $\delta_{B}=7.27$ ) overlapping with the chloroform signal present in deuteriochloroform ( $99.5 \%$ $\mathrm{CDCl}_{3}, 0.5 \% \mathrm{CHCl}_{3}$ ) with a typical trans coupling of ${ }^{3} J_{A B}=16 \mathrm{~Hz}$ reveals a CC double bond $\mathbf{B}$ with protons in trans configuration. An $A A^{\prime} X X^{\prime}$-four-spin system ( $\delta_{A A^{\prime}}=7.67$ and $\delta_{X X}=7.89$, two protons for each signal according to the integral levels) indicates a $p$-disubstituted benzenoid ring C. The three remaining signals which include five protons according to the integral levels ( $\delta_{A}=$ $7.32, \delta_{M M^{\prime}}=7.40$ and $\delta_{X X^{\prime}}=7.50$ ) belong to a monosubstituted benzene ring $\mathbf{D}$.

$\bar{\delta}_{H}=10.0 \mathrm{~s}$
A

${ }^{3} J_{A B}=16 \mathrm{~Hz}$
B

C

D

Rational arrangement of these partial structures leads to trans-stilbene-4-aldehyde $\mathbf{E}$.

E

F

The alternative trans-p-phenylcinnamic aldehyde F would display an additional ${ }^{3} J_{H H}$ coupling between the aldehyde proton and the vicinal alkene proton of the double bond which is not observed in spectrum 8 (but in spectrum 4 for comparison).
Protons of substructure $\mathbf{B}$ and $\mathbf{C}$ are assigned by means of the mesomeric effect of the aldehyde group which deshields the protons in o-position of the attached $p$-disubstituted benzenoid ring and in $\beta$-position of the central CC double bond; ortho-protons of the monosubstituted benzenoid ring D split into a doublet because of one ortho coupling ( 7.5 Hz ) while the meta-protons split into a triplet because of two ortho couplings.

## 9 6,4'-Dimethoxyisoflavone

Two intense signals at $\delta_{H}=3.70$ and 3.80 identify two methoxy groups as substituents. The benzenoid proton resonances arise from two subspectra, an $A A^{\prime} X X^{\prime}$ system ( $\delta_{A A^{\prime}}=6.83, \delta_{X X}=7.37$ ) and an $A B X$ system ( $\delta_{A}=7.11, \delta_{B}=7.26, \delta_{X}=7.51$ ). The $A A^{\prime} X X^{\prime}$ part spectrum indicates a paradisubstituted benzene ring, and locates one methoxy group in the 4 '-position of the phenyl ring $B$. A doublet of doublets with ortho and meta coupling ( 9 and 3 Hz , respectively) belongs to the $A B X$ system, from which a $1,2,4$-trisubstituted benzene ring (ring $A$ ) is derived. Hence the solution is isomer 6,4'- or 7,4'-dimethoxyisoflavone $\mathbf{A}$ or $\mathbf{B}$.
A

The decisive clue is given by the large shift ( $\delta_{H}=7.51$ ) of the proton marked with an asterisk, which only shows one meta coupling. This shift value fits structure $\mathbf{A}$, in which the $-M$ effect and the anisotropy effect of the carbonyl group lead to deshielding of the proton in question. In $\mathbf{B}$ the $+M$ effect of the two ortho oxygen atoms would lead to considerable shielding. The methoxy resonances cannot be assigned conclusively to specific methoxy groups in the presented spectrum.

## 10 Catechol (3,5,7,3',4'-pentahydroxyflavane)

Sesquiterpenes and flavonoids (flavones, flavanones, flavanes) are two classes of natural substances which occur frequently in plants and which have 15 C atoms in their framework. The nine
double-bond equivalents which are contained in the empirical formula, ${ }^{l} H$ signals in the region appropriate for shielded benzene ring protons ( $\delta_{H}=5.9-6.9$ ) and phenolic OH protons ( $\delta_{H}=7.9$ 8.3) indicate a flavonoid.

In the ${ }^{l} H$ NMR spectrum five protons can be exchanged by deuterium. Here the molecular formula permits only OH groups. The shift values ( $\delta_{H}$ above 7.9 ) identify four phenolic OH groups and one less acidic alcoholic OH function ( $\delta_{H}=4.0$, overlapping).
Between $\delta_{H}=5.8$ and 6.1 the ${ }^{l} H$ signals appear with typical ortho and meta couplings. The small shift values show that the benzene rings are substituted by electron donors ( OH groups). In this region two subspectra can be discerned: an $A B$ system with a meta coupling ( 2.2 Hz ) identifies a tetrasubstituted benzene ring $\mathbf{A}$ with meta $H$ atoms; an $A B M$ system with one ortho and one meta coupling ( 8.1 and 1.9 Hz , respectively) indicates a second benzene ring $\mathbf{B}$ with a $1,2,4$-arrangement of the $H$ atoms. Eight of the nine double-bond equivalents are thus assigned places.

Following the principle that the coupling partner will have the same coupling constant, one can identify in the aliphatic region a $\mathrm{C}_{3}$ chain as a further part structure, $\mathbf{C}$.

Assembly of fragments A-C, taking into account the ninth double-bond equivalent, leads to the $3,5,7,3^{\prime}, 4^{\prime}$-pentahydroxyflavane skeleton $\mathbf{D}$ and to the following assignment of ${ }^{l} H$ chemical shifts:

The relative configurations of phenyl ring $\mathbf{B}$ and the OH groups on ring $\mathbf{C}$ follows from the antiperiplanar coupling ( 8.3 Hz ) of the proton at $\delta_{H}=4.56$. The coupling partner $3-\mathrm{H}$ at $\delta_{H}=4.0$ shows this coupling a second time (pseudotriplet 't' with 8.3 Hz of doublets $d$ with 5.0 Hz ), because one of the neighbouring methylene protons is also located in a position which is antiperiplanar relative to $3-H(8.3 \mathrm{~Hz})$ and another is located $\operatorname{syn}$ relative to $3-\mathrm{H}(5.0 \mathrm{~Hz})$. Hence one concludes that this compound is catechol or its enantiomer. The stereoformula $\mathbf{E}$ shows those coupling constants ( Hz ) which are of significance for deriving the relative configuration.
E

## 11 Methyloxirane and monordene

The relationship ( ${ }^{3} J_{\text {cis }}>{ }^{3} J_{\text {trans }}$; cf. problem 1), which applies to cyclopropane, also holds for the vicinal couplings of the oxirane protons (spectrum 11a) with the exception that here values are smaller owing to the electronegative ring oxygen atoms. As spectrum 11a shows, the cis coupling has a value of 3.9 Hz whereas the trans coupling has a value of 2.6 Hz . The proton at $\delta_{H}=2.84$ is thus located cis relative to the proton at $\delta_{H}=2.58$ and trans relative to the proton at $\delta_{H}=2.28$. The coupling partners can be identified by their identical coupling constants where these can be read off precisely enough. Thus the methyl protons couple with the vicinal ring protons ( 5.1 Hz ), the cis ring protons $(0.4 \mathrm{~Hz})$ and the trans ring protons $(0.5 \mathrm{~Hz})$; however, the small difference between these long-range couplings cannot be resolved in the methyl signal because of the large half-width, so that what one observes is a pseudotriplet.

Again following the principle that the same coupling constant holds for the coupling partner, the ${ }^{I} H$ shift values of the protons on the positions $\mathrm{C}-1$ to $\mathrm{C}-9$ of monordene can be assigned $\left(\mathbf{A}, \delta_{H}\right)$, as can the multiplicities and the coupling constants ( $\mathbf{B}, \mathrm{Hz}$ ).

The relative configurations of vicinal protons follow from the characteristic values of their coupling constants. Thus 16.1 Hz confirms the trans relationship of the protons on C-8 and C-9, 10.8 Hz confirms the cis relationship of the protons on C-6 and C-7. The 2.0 Hz coupling is common to the oxirane protons at $\delta_{H}=3.00$ and 3.27; this value fixes the trans relationship of the protons at $\mathrm{C}-4$ and $\mathrm{C}-5$ following a comparison with the corresponding coupling in the methyloxirane (2.6 $H z$ ). The anti relationship of the protons $4-H$ and $3-H^{A}$ can be recognised from their 8.7 Hz coup-
ling in contrast to the syn relationship between $3-H^{B}$ and $4-H(3.1 \mathrm{~Hz})$. Coupling constants which are almost equal in value ( $3.2-3.7 \mathrm{~Hz}$ ) linking $2-H$ with the protons $3-H^{A}$ and $3-H^{B}$ indicate its syn relationship with these protons ( $3-H^{A}$ and $3-H^{B}$ straddle 2- $H$ ).

The absolute configuration, $(2 S, 4 S, 5 S)$ as shown or $(2 R, 4 R, 5 R)$, cannot be deduced by NMR. For larger structures the insertion of the shift values and the coupling constants in the stereo projection of the structural formula, from which one can construct a Dreiding model, proves useful in providing an overview of the stereochemical relationships.

## 12 2-Methyl-6-(N,N-dimethylamino)-trans-4-nitro-trans-5-phenylcyclohexene

An examination of the cross signals of the $H H$ COSY diagram leads to the proton connectivities shown in $\mathbf{A}$ starting from the alkene proton at $\delta_{H}=5.67$.

Strong cross signals linking the $\mathrm{CH}_{2}$ group $\left(\delta_{H}=2.34\right)$ with the proton at $\delta_{H}=3.36$ confirm the regioselectivity of the Diels-Alder reaction and indicate the adduct $\mathbf{B}$ : the $\mathrm{CH}_{2}$ is bonded to the phenyl- CH rather than to the nitro- CH group; if it were bonded to the later, then cross signals for $\delta_{H}=2.34$ and 5.12 would be observed.

The relative configuration $\mathbf{C}$ is derived from the coupling constants of the ${ }^{l} H$ NMR spectrum: the 11.9 Hz coupling of the phenyl-CH proton $\left(\delta_{H}=3.36\right)$ proves its antiperiplanar relationship to the
nitro-CH proton $\left(\delta_{H}=5.12\right)$. In its doublet of doublets signal a second antiperiplanar coupling of 9.2 Hz appears in addition to the one already mentioned, which establishes the anti positon of the CH proton at $\delta_{H}=4.10$ in the positon $\alpha$ to the $N, N$-dimethylamino group.

*: couplings are not observed for the $A_{2}$ system of methylene protons

## 13 (E)-3-(N,N-Dimethylamino)acrolein

First the trans configuration of the $\mathrm{C}-2-\mathrm{C}-3$ double bond is derived from the large coupling constant $\left({ }^{3} J_{H H}=13 \mathrm{~Hz}\right)$ of the protons at $\delta_{H}=5.10$ and 7.11 , whereby the middle CH proton ( $\delta_{H}=$ 5.10) appears as a doublet of doublets on account of the additional coupling ( 8.5 Hz ) to the aldehyde proton.

The two methyl groups are not equivalent at 303 K ( $\delta_{H}=2.86$ and 3.14 ); rotation about the CN bond is 'frozen', because this bond has partial $\pi$ character as a result of the mesomeric (resonance) effects of the dimethylamino group ( $+M$ ) and of the aldehyde function ( $-M$ ), so that there are cis and trans methyl groups. Hence one can regard 3-( $N, N$-dimethylamino) acrolein as a vinylogue of dimethylformamide and formulate a vinylogous amide resonance.
At 318 K the methyl signals coalesce. The half-width $\Delta v$ of the coalescence signal is approximately equal to the frequency separation of the methyl signals at 308 K ; its value is $\Delta \delta_{I I}=3.14-2.86$ $=0.28$, which at 250 MHz corresponds to $\Delta v=70 \mathrm{~Hz}$. The following exchange or rotation frequency of the $\mathrm{N}, \mathrm{N}$-dimethylamino group is calculated at the coalescence temperature:

$$
k=(\pi / \sqrt{2}) \times \Delta v=155.5 \mathrm{~s}^{-1}
$$

Finally from the logarithmic form of the Eyring equation, the free enthalpy of activation, $\Delta G$, of rotation of the dimethylamino group at the coalescence temperature ( 318 K ) can be calculated:

```
\DeltaGG18}=19.134 Tc[10.32+\operatorname{log}(\mp@subsup{T}{c}{}\sqrt{}{2}/\pi\Deltav)]\times10-3 kJmol-1
    = 19.134\times318[10.32+酋(318\times1.414/3.14\times70)]\times10-3
    = 19.134 \times 318(10.32+0.311)\times10-3
    = 64.7 kJ mo+1 ( }15.45\mp@subsup{\textrm{kcal mo卜}}{}{-1}
```

## 14 cis-1,2-Dimethylcyclohexane

The temperature dependence of the ${ }^{13} \mathrm{C}$ NMR spectrum is a result of cyclohexane ring inversion. At room temperature ( 298 K ) four average signals are observed instead of the eight expected signals for the non-equivalent C atoms of cis-1,2-dimethylcyclohexane. Below $-20^{\circ} \mathrm{C}$ ring inversion occurs much more slowly and at $-50^{\circ} \mathrm{C}$ the eight expected signals of the conformers I and II appear.

The coalescence temperatures lie between 243 and 253 K and increase as the frequency difference between the coalescing signals in the 'frozen' state increases. Thus the coalescence temperature for the pairs of signals at $\delta_{\mathrm{C}}=35.2 / 33.3$ lies between 238 and 243 K ; owing to signal overlap the coalescence point cannot be detected precisely here. The methyl signals at $\delta_{\mathrm{C}}=20.5$ and 11.5 have a larger frequency difference ( $\Delta \delta_{\mathrm{C}}=9$ or $\Delta v=900 \mathrm{~Hz}$ at 100 MHz ) and so coalesce at 253 K , a fact which can be recognised from the plateau profile of the average signal ( $\delta_{\mathrm{C}}=16.4$ ). Since the frequency difference of this signal $(900 \mathrm{~Hz})$ in the 'frozen' state $(223 \mathrm{~K})$ may be measured more precisely than the width at half-height of the coalescing signal at 253 K , the exchange frequency $k$ of the methyl groups is calculated from $\Delta v$ :

$$
k=(\pi N \sqrt{2}) \times 900=1998.6 \mathrm{~s}-1
$$

The frce enthalpy of activation, $\Delta G$, of the ring inversion at 253 K is calculated from the logarithmic form of the Eyring equation:

```
    = 19.134\times253[10.32+酋(253\times1.414/3.14\times900)] 10-3
    = 19.134 \times253(10.32-1.9)\times10-3
    = 40.8 kJ mot-1 (9.75 kcal mot-1)
```

The assignment of resonances in Table 14.2 results from summation of substituent effects as listed in Table 14.1. The data refer to conformer I; for conformer II the C atoms pairs $\mathrm{C}-1 / \mathrm{C}-2, \mathrm{C}-3 / \mathrm{C}-6$, $\mathrm{C}-4 / \mathrm{C}-5$ and $\mathrm{C}-7 / \mathrm{C}-8$ change places.

Table 14.1. Prediction of ${ }^{13} \mathrm{C}$ chemical shift of cis-I,2-dimethylcyclohexane in the 'frozen' state, using the cyclohexane sinift of $\delta_{c}-27.6$ and substituent effecis (e.g. Ref. 0 , $\mu .310$ )

## 15 5-Ethynyl-2-methylpyridine

The ${ }^{13} \mathrm{C}$ NMR spectrum illustrates the connection between carbon hybridisation and ${ }^{13} \mathrm{C}$ shift on the one hand and $J_{\mathrm{CH}}$ coupling constants on the other.
The compound clearly contains a methyl group ( $\delta_{\mathrm{C}}=24.4$, quartet, $J_{\mathrm{CH}}=127.5 \mathrm{~Hz}, \mathrm{sp}^{3}$ ) and an ethynyl group ( $\delta_{\mathrm{C}}=80.4$, doublet, $J_{\mathrm{C} H}=252.7 \mathrm{~Hz}, \mathrm{sp} ; \delta_{\mathrm{C}}=80.8$, a doublet as a result of the coupling ${ }^{2} J_{\mathrm{CH}}=47.0 \mathrm{~Hz}$ ). Of the five signals in the $\mathrm{sp}^{2}$ shift range, three belong to CH units and two to quaternary carbon atoms on the basis of the ${ }^{l} J_{\mathrm{CH}}$ splitting (three doublets, two singlets). The coupling constant $J_{\mathrm{CH}}=182.5 \mathrm{~Hz}$ for the doublet centred at $\delta_{\mathrm{C}}-152.2$ therefore indicates a disubstituted pyridine ring $\mathbf{A}$ with a $\mathbf{C H}$ unit in one $\alpha$-position. It follows from the shift of the quaternary C atom that the methyl group occupies the other $\alpha$-position ( $\delta_{\mathrm{C}}=158.4, \alpha$-increment of a methyl group, about 9 ppm , on the $\alpha-\mathrm{C}$ atom of a pyridine ring, approximately $\delta_{\mathrm{C}}=150$ ); the shielding ethynyl group occupies a $\beta$-position, as can be seen from the small shift of the second quaternary $\mathbf{C}$ atom $\left(\delta_{\mathrm{C}}=116.4\right)$. From this, two regioisomers $\mathbf{B}$ and $\mathbf{C}$ appear possible.

A

B

C

The additional doublet splitting ( ${ }^{3} J_{\mathrm{CH}}=2.4 \mathrm{~Hz}$ ) of the methyl quartet decides in favour of $\mathbf{C}$; long range coupling in $\mathbf{B}\left({ }^{4} J_{\mathrm{C} H},{ }^{5} J_{\mathrm{CH}}\right)$ of the methyl C atom to $H$ atoms of the ethynyl group and of the pyridine ring would not have been resolved in the spectrum. The long range quartet splitting of the pyridine CH signal at $\delta_{\mathrm{C}}=122.7\left(\mathrm{C}-3,{ }^{3} J_{\mathrm{C} H}=3.7 \mathrm{~Hz}\right)$ confirms the 2-position of the methyl group and thus locates the ethynyl group in the 5 -position, as in $\mathbf{C}$.

## 16 5-Hydroxy-3-methyl-1H-pyrazole

The compound referred to as 3-methylpyrazolone $\mathbf{A}$ ought to show a quartet and a triplet in the aliphatic region, the former for the ring $\mathrm{CH}_{2}$ group. However, only a quartet is observed in the $\mathrm{sp}^{3}$ shift range in hexadeuteriodimethyl sulphoxide whilst at $\delta_{\mathrm{C}}=89.2$ a doublet is found with $J_{\mathrm{CH}}=$ 174.6 Hz . An $\mathrm{sp}^{2}$-hybridised C atom with two cooperating $+M$ effects fits the latter, the effect which OH and ring $\mathrm{N} H$ groups have in 5 -hydroxy-3-methyl-1 $H$-pyrazole $\mathbf{B}$. The very strong shielding ( $\delta_{\mathrm{C}}=89.2$ ) could not be explained by $\mathrm{N} H$ tautomer $\mathbf{C}$, which would otherwise be equally viable; in this case only a $+M$ effect of the ring $\mathrm{N} H$ group would have any influence.

## 17 o-Hydroxyacetophenone

The compound contains five double-bond equivalents. In the ${ }^{13} \mathrm{C}$ NMR spectrum all eight C atoms of the molecular formula are apparent, as a $\mathrm{CH}_{3}$ quartet ( $\delta_{\mathrm{C}}=26.6$ ) four CH doublets ( $\delta_{\mathrm{C}}=118$ 136 ) and three singlets ( $\delta_{\mathrm{C}}=120.0,162.2,204.9$ ) for three quaternary C atoms. The sum of these fragments $\left(\mathrm{CH}_{3}+\mathrm{C}_{4} H_{4}+\mathrm{C}_{3}=\mathrm{C}_{8} H_{7}\right)$ gives only seven $H$ atoms which are bonded to C ; since the molecular formula only contains oxygen as a heteroatom, the additional eighth $H$ atom belongs to an OH group.
Since two quaternary atoms and four CH atoms appear in the ${ }^{13} \mathrm{C}$ NMR spectrum, the latter with a benzenoid ${ }^{3} J_{\mathrm{CH}}$ coupling constant of $7-9 \mathrm{~Hz}$, this is a disubstituted benzene ring, and the C signal with $\delta_{\mathrm{C}}=162.2$ fits a phenoxy C atom. The keto carbonyl $\left(\delta_{\mathrm{C}}=204.9\right)$ and methyl ( $\delta_{\mathrm{C}}=26.6$ ) resonances therefore point to an acetyl group as the only meaningful second substituent. Accordingly, it must be either $o$ - or $m$-hydroxyacetophenone $\mathbf{A}$ or $\mathbf{B}$; the para isomer would show only four benzenoid ${ }^{13} \mathrm{C}$ signals because of the molecular symmetry.

A

B

It would be possible to decide between these two by means of substituent effects, but in this case a conclusive decision is reached using the ${ }^{3} J_{C H}$ coupling: the C atom marked with an asterisk in $\mathbf{B}$ would show no ${ }^{3} J_{\mathrm{CH}}$ coupling, because the meta positions are substituted. In the coupled ${ }^{13} \mathrm{C}$ NMR spectrum, however, all of the CH signals are split with ${ }^{3} J_{C H}$ couplings of $7-9 \mathrm{~Hz}$. The ${ }^{3} J_{\mathrm{CH}}$ pseudotriplet splitting of the resonance at $\delta_{\mathrm{C}}=118.2$ argues in favour of $\mathbf{A}$; the origin of the additional
${ }^{3} J_{\mathrm{CH}}$ coupling of the C atom marked with an asterisk in $\mathbf{A}$ is the intramolecular hydrogen bonding proton. This coupling also permits straightforward assignment of the closely spaced signals at $\delta_{\mathrm{C}}=$ 118.2 (C-3) and 119.2 (C-5).

## 18 Potassium 1-acetonyl-2,4,6-trinitrocyclohexa-2,5-dienate

The ${ }^{13} \mathrm{C}$ NMR spectrum shows from the signals at $\delta_{C}=205.6$ (singlet), 47.0 (triplet) and 29.8 (quartet) that the acetonyl residue with the carbonyl group intact ( $\delta_{\mathrm{C}}=205.6$ ) is bonded to the trinitrophenyl ring. Only three of the four signals which are expected for the trinitrophenyl ring from the molecular symmetry (C-1, C-2,6, C-3,5, C-4) are found here ( $\delta_{\mathrm{C}}=133.4,127.6,121.6$ ); however, a further doublet signal ( $\delta_{\mathrm{C}}=34.5$ with $J_{\mathrm{CH}}=145.6 \mathrm{~Hz}$ ) appears in the aliphatic shift region. This shows that the benzene CH unit rehybridises from trigonal $\left(\mathrm{sp}^{2}\right)$ to tetrahedral $\left(\mathrm{sp}^{3}\right)$, so that a Meisenheimer salt $\mathbf{A}$ is produced.

Signal assignment is then no problem; the C atoms which are bonded to the nitro groups C-2,6 and $\mathrm{C}-4$ are clearly distinguishable in the ${ }^{13} \mathrm{C}$ NMR spectrum by the intensities of their signals.

## 19 trans-3-[4-( $\mathrm{N}, \mathrm{N}$-Dimethylamino)phenyl]-2-ethylpropenal

The relative configuration at the CC double bond can be derived from the ${ }^{3} J_{C H}$ coupling of the aldehyde ${ }^{13} \mathrm{C}$ signal at $\delta_{\mathrm{C}}=195.5$ in the coupled ${ }^{13} \mathrm{C}$ NMR spectrum; as a result of this coupling, a doublet (with 11.0 Hz ) of triplets (with 4.9 Hz ) is observed. The 11.0 Hz coupling points to a cis configuration of aldehyde C and alkene $H$; the corresponding trans coupling would have a value of $c a 15 \mathrm{~Hz}$ (reference substance: methacrolein, Table 2.11 ). The aldehyde and $p$-dimethylaminophenyl groups therefore occupy trans positions.

## 20 N -Butylsalicylaldimine

In the ${ }^{13} \mathrm{C}$ NMR spectrum the signal of the $O$-trimethylsilyl group is missing near $\delta_{\mathrm{C}}=0$. Instead there is a doublet ( ${ }^{l} J_{\mathrm{C} H}=159.3 \mathrm{~Hz}$ ) of quartets $\left({ }^{3} J_{\mathrm{C} H}=6.1 \mathrm{~Hz}\right)$ at $\delta_{\mathrm{C}}=164.7$ for an imino C atom and a triplet of multiplets at $\delta_{\mathrm{C}}=59.0$. Its ${ }^{l} J_{\mathrm{CH}}$ coupling of 141.6 Hz points to an $\mathrm{N}-\mathrm{CH}_{2}$ unit as part of an $n$-butyl group with further signals that would fit this arrangement at $\delta_{C}=33.0,20.3$ and 13.7. The product of the reaction is therefore salicylaldehyde $N$-( $n$-butyl)imine. Assignment of the individual shifts for the hydrocarbon pair C-3/C-5, which are shielded by the hydroxy group as a $+M$ substituent in the ortho and para position, respectively, is achieved by observing the possible long-range couplings: C-6 couples with 1.8 Hz to $7-\mathrm{H}$; C-3 is broadened as a result of coupling with the $H$-bonding OH . Both the latter and the cis coupling of $\mathrm{C}-\alpha$ with $7-H(7.3 \mathrm{~Hz})$ point to the $E$-configuration of N -butyl and phenyl relative to the imino double bond.

## 21 Benzo[b]furan

All ${ }^{13} \mathrm{C}$ signals appear in the region appropriate for $\mathrm{sp}^{2}$-hybridised C atoms; hence it could be an aromatic, a heteroaromatic or a polyene. If the matching doublet contour signals ( $\cdot$ ) along the orthogonals of the INADEQUATE experiment are connected (A) then the result is eight CC bonds, six of which relate to the benzene ring. For example, one can begin with the signal at $\delta_{\mathrm{C}}=$ 107.3 and deduce the hydrocarbon skeleton $\mathbf{A}$.

A

The coupled ${ }^{13} \mathrm{C}$ NMR spectrum identifies the C atoms at $\delta_{\mathrm{C}}=145.7$ and 155.9 as CH and C , respectively, whose as yet unattached bonds go to an electron-withdrawing heteroatom which causes the large shift values. The CH signals which are not benzenoid, at $\delta_{\mathrm{C}}=107.3$ and 145.7 , show remarkably large coupling constants ( 177.2 and 201.7 Hz , respectively) and long-range couplings (12.7 and 11.6 Hz ). These data are consistent with a 2,3-disubstituted furan ring (Tables 2.6 and 2.7); benzo[ $b]$ furan $\mathbf{B}$ is therefore the result.

| ${ }^{13} \mathrm{C}$ chemical shifts $\delta_{C}$ | CH multiplicities, CH coupling constants $(\mathrm{Hz})$, coupling protons |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 112.1 | C-2 | D | 201.7 | d | 11.6 | (3-H) |  |  |
| 125.1 / 77 | C-3 | D | 177.2 | d | 12.7 | (2-H) | d | 3.0 (4-H) |
|  | C-3a | S |  | m |  |  |  |  |
| $123.6 \times 128.4107 .3$ | C-4 | D | 163.0 | d | 7.4 | (6-H) |  |  |
| 122.0 | C-5 | D | 162.3 | d | 8.9 | (7-H) |  |  |
| B | C-6 | D | 159.2 | d | 7.4 | (4-H) |  |  |
|  | C-7 | D | 160.0 | d | 6.7 | (5-H) | d | $1.5(6-H / 3-H)$ |
|  | C-7a | S |  | m |  |  |  |  |

Additional CC correlation signals ( $\delta_{\mathrm{C}}=145.7$ to $122.0 ; 128.4$ to $125.1 ; 122.0$ to 112.1 ) are the result of ${ }^{3} J_{\mathrm{CC}}$ coupling and confirm the assignments given above.

## 22 3-Hydroxypropyl 2-ethylcyclohexa-1,3-diene-5-carboxylate

The cross signals in the INADEQUATE plot show the CC bonds for two part structures $\mathbf{A}$ and $\mathbf{B}$. Taking the ${ }^{13} \mathrm{C}$ signal at $\delta_{\mathrm{C}}=174.1$ as the starting point the hydrocarbon skelcton $\mathbf{A}$ and additional $\mathrm{C}_{3}$ chain $\mathbf{B}$ result.

Part structure $\mathbf{A}$ is recogniscd to be a 2,5 -disubstituted cyclohexa-1,3-diene on the basis of its chemical shift values. The ethyl group is one substituent, the other is a carboxy function judging by the chemical shift value of $\delta_{\mathrm{C}}=174.1$. The CH multiplicities which follow from the DEPT subspectra, $2 \mathrm{C}, 4 \mathrm{CH}, 5 \mathrm{CH}_{2}$ and $\mathrm{CH}_{3}$, lead to the CH part formula $\mathrm{C}_{2}+\mathrm{C}_{4} \mathrm{H}_{4}+\mathrm{C}_{5} H_{10}+\mathrm{CH}_{3}=$ $\mathrm{C}_{12} \mathrm{H}_{l 7}$. Comparison with the given molecular formula, $\mathrm{C}_{12} \mathrm{H}_{18} \mathrm{O}_{3}$, indicates an OH group. Since
the C atoms at $\delta_{\mathrm{C}}=62.1$ and 58.6 are linked to oxygen according to their shift values and according to the molecular formula, $\mathbf{A}$ and $\mathbf{B}$ can be added together to form 3-hydroxypropyl 2-ethyl-cyclohexa-1,3-diene-5-carboxylate $\mathbf{C}$.

The assignment of $\mathrm{C}-\alpha^{\prime}$ and $\mathrm{C}-\gamma^{\prime}$ is based on the larger deshielding of $\mathrm{C}-\alpha^{\prime}$ by the two $\beta-\mathrm{C}$ atoms ( $\mathrm{C}-\boldsymbol{\gamma}^{\prime}$ and $\mathrm{C}=\mathrm{O}$ ).

## 23 Hex-3-yn-1-ol

All six of the C atoms found in the molecular formula appear in the ${ }^{13} \mathrm{C}$ NMR spectrum. Interpretation of the ${ }^{l} J_{\mathrm{CH}}$ multiplets gives one $\mathrm{CH}_{3}$ group ( $\delta_{\mathrm{C}}=14.4$ ), three $\mathrm{CH}_{2}$ groups ( $\delta_{\mathrm{C}}=12.6,23.2$ and 61.6) and two quaternary C atoms ( $\delta_{\mathrm{C}}=76.6$ and 83.0). The addition of these CH fragments $\left(\mathrm{CH}_{3}+\mathrm{C}_{3} H_{6}+\mathrm{C}_{2}\right)$ produces $\mathrm{C}_{6} H_{9}$; the additional $H$ atom in the molecular formula therefore belongs to an OH group. This is a part of a primary alcohol function $\mathrm{CH}_{2} \mathrm{OH}$, because a ${ }^{13} \mathrm{C}$ shift of $\delta_{\mathrm{C}}=61.6$ and the corresponding splitting (triplet, ${ }^{l} J_{\mathrm{CH}}=144.0 \mathrm{~Hz}$ ) reflect the $-I$ effect of an attached O atom. The long-range triplet splitting of the $\mathrm{CH}_{2} \mathrm{O}$ signal ( 6.3 Hz ) indicates a neighbouring $\mathrm{CH}_{2}$ group. This hydroxyethyl partial structure $\mathbf{A}$ is evident in the ${ }^{l} H$ NMK spectrum also, in which the coupling proton may be identified by the uniformity of its coupling constants.

Obviously the exchange frequency of the OH protons is small in comparison with the coupling constant ( 4.9 Hz ), so coupling between the OH and $\mathrm{CH}_{2}$ protons also causes additional splitting of the ${ }^{l} H$ signals ( $\delta_{H}=3.58$ and 4.72).
The additional triplet splitting ( 2.2 Hz ) of the $\mathrm{CH}_{2}$ protons (at $\delta_{H}=2.32$ ) is the result of long-range coupling to the third $\mathrm{CH}_{2}$ group of the molecule, which can be recognised at $\delta_{H}=2.13$ by the same fine structure. The larger coupling constant $(7.6 \mathrm{~Hz})$ is repeated in the triplet at $\delta_{H}=1.07$, so that an ethyl group is seen as a second structural fragment $\mathbf{B}$ in accordance with the further signals in the ${ }^{13} \mathrm{C}$ NMR spectrum ( $\delta_{\mathrm{C}}=12.6, \mathrm{~T} 130.4 \mathrm{~Hz}$, and $\delta_{\mathrm{C}}=14.4, \mathrm{Q} 127.9 \mathrm{~Hz}, \mathrm{t} 5.4 \mathrm{~Hz}$ ).

The long-range coupling of 2.2 Hz which appears in $\mathbf{A}$ and $\mathbf{B}$, two quaternary C atoms in the ${ }^{13} \mathrm{C}$ NMR spectrum with appropriate shifts ( $\delta_{\mathrm{C}}=76.6$ and 83.0 ) and the two double-bond equivalents (molecular formula $\mathrm{C}_{6} H_{10} \mathrm{O}$ ) suggest that a CC triple bond links the two structural fragments. Hence the compound is identified as hex-3-yn-1-ol (C) in accordance with the coupling patterns.

## 24 N,N-Diethylamino)ethyl 4-aminobenzoate hydrochloride (procaine hydrochloride)

The discussion centres on the two structural formulae $\mathbf{A}$ and $\mathbf{B}$.

A

B

A choice can be made between these two with the help of published ${ }^{13} \mathrm{C}$ substituent effects ${ }^{5,6} Z_{i}$ for the substituents $\left(-\mathrm{NH}_{2},-\mathrm{NH}_{3}{ }^{+},-\mathrm{COOR}\right.$; see Section 2.5.4) on the benzene ring in $\mathbf{A}$ and $\mathbf{B}$ :

| Substituent | $Z_{1}$ | $Z_{o}$ | $Z_{m}$ | $Z_{\rho}$ |
| :--- | ---: | ---: | ---: | ---: |
| $-\mathrm{NH}_{2}$ | 18.2 | -13.4 | 0.8 | -10.0 |
| $-\mathrm{NH}_{3}{ }^{+}$ | 0.1 | -5.8 | 2.2 | 2.2 |
| $-\mathrm{CO}_{2} \mathrm{C}_{2} \mathrm{H}_{5}$ | 2.1 | -1.0 | -0.5 | -3.9 |

Adding these substituent effects gives the following calculated shift valucs (as compared with the observed values in parentheses) for $\mathbf{C}-1$ to $\mathrm{C}-4$ of the para-disubstituted benzene ring in $\mathbf{A}$ and $\mathbf{B}$ :

Substituent effects calculated for structure B lead to values which are not perfect but which agree more closely than for $\mathbf{A}$ with the measured ${ }^{13} \mathrm{C}$ shifts of the benzene ring carbon atoms. The diastereotopism of the $\mathrm{NCH}_{2}$ protons in the ${ }^{l} H$ NMR spectrum also points to $\mathbf{B}$ as the Newman projection $\mathbf{C}$ along the $\mathrm{CH}_{2}-$ ammonium- N bond shows:

Hence one finds two overlapping pseudotriplets ( $\delta_{H}=3.41$ and 3.44) for the $\mathrm{NCH}_{2}$ group which appears only once and two overlapping quartets ( $\delta_{H}=3.22$ and 3.25 ) for the $\mathrm{NCH}_{2}$ groups which appear twice. Since the shift differences of the $\mathrm{CH}_{2}$ protons are so small, the expected $A B$ systems of the coupling partners approximate to $A_{2}$ systems at 200 MHz ; thus one observes only the central multiplet signals of these $A B$ systems.
The assignment of the ${ }^{13} \mathrm{C}$ NMR spectrum is based on the different ${ }^{l} J_{\mathrm{C} H}$ coupling constants of $\mathrm{OCH}_{2}\left(149.4 \mathrm{~Hz}\right.$ ) and $\mathrm{NCH}_{2}$ groups ( $140-142 \mathrm{~Hz}$ ). With benzenoid ${ }^{3} J_{\mathrm{CH}}$ couplings the influence of the different electronegativities of the substituents on the coupling path ( 4.5 Hz for $\mathrm{NH}_{2}$ and 6.6 Hz for $\mathrm{CO}_{2} \mathrm{R}$ ) and on the coupling C atom is very obvious ( 8.8 Hz for $\mathrm{NH}_{2}$ at $\mathrm{C}-4$ and 7.7 Hz for $\mathrm{CO}_{2} \mathrm{R}$ at $\mathrm{C}-1$ ).

## 25 5,5'-Bis-(hydroxymethyl)-2,2'-bifuran

The ${ }^{13} \mathrm{C}$ NMR spectrum displays five instead of ten carbon signals as expected from the empirical formula $\mathrm{C}_{10} H_{i 0} \mathrm{O}_{4}$. To conclude, two identical halves $\mathrm{C}_{5} \mathrm{I}_{5} \mathrm{O}_{2}$ build up the molecular structure.
With oxygen as heteroatom in the empirical formula and according to the coupling constants of aromatic and heteroaromatic compounds listed in Table 2.5, the $A X$ system with $\delta_{A}=6.38, \delta_{X}=$ 6.56 and $J_{A X}=3.5 \mathrm{~Hz}$ in the ${ }^{l} H$ NMR spectrum reveals a 2,5 -disubstituted furan ring A, matching well to ${ }^{3} J_{3,4}=3.4 \mathrm{~Hz}$ but neither to ${ }^{3} J_{H H}=1.8 \mathrm{~Hz}$ for $2,3-$ nor to ${ }^{4} J_{H H}=1.5 \mathrm{~Hz}$ for $3,4-$ nor to ${ }^{4} J_{H H}$ $=0.9 \mathrm{~Hz}$ for 2,4-disubstitution. This agrees with two non-protonated carbons, both deshielded by an adjacent ring oxygen ( $\delta_{\mathrm{C}}=155.4$ and 145.2), and two CH carbon signals ( $\delta_{\mathrm{C}}=109.2$ and 106.1, doublets with one-bond couplings $J_{\mathrm{CH}}=175.7$ and 176.6 Hz , respectively), both shielded by the $+M$ effect of the ring oxygen two bonds apart.

According to their integral levels (2:1), the remaining proton signals represent an $A_{2} X$ system with $\delta_{A}=4.41, \delta_{X}=5.31$ and $J_{A X}=6.0 \mathrm{~Hz}$. These protons arise from a hydroxymethylene group B because the ${ }^{13} \mathrm{C}$ NMR spectrum shows one CH triplet with $\delta_{\mathrm{C}}=55.9$ but no additional CH doublet signal. ${ }^{3} J_{H H}$ coupling ( 6.0 Hz ) between $\mathrm{CH}_{2}$ and OH protons is observed in this sample solution because solvation of the alcohol by hexadeuterioacetone prevents exchange by intermolecular hydrogen bonding.

Partial structures $\mathbf{A}$ and $\mathbf{B}$ attached to each other represent one half $\left(\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{O}_{2}\right)$ of the molecule according to the empirical formula $\left(\mathrm{C}_{10} \mathrm{H}_{10} \mathrm{O}_{4}\right)$. Therefore, the compound is $5,5^{\prime}$-dihydroxymethyl-$2,2^{\prime}$-bifuran $\mathbf{C}$. Carbon signals of the furan rings are assigned by means of two- and three-bond carbon-proton couplings as explained in the table. The proton signal of the furan ring proton $\delta_{A}=$ 6.38 ) is slightly broadened by non-resolved allylic coupling ( ${ }^{4} J_{H H}$ ) to the methylene protons and, due to this, it is assigned.

## 26 N-Methyl-6,7-methylenedioxy-1-0x0-1,2,3,4-tetrahydroisoquinoline

The integral levels ( $\sim 1: 1: 2: 2: 3: 2$ ) of the proton signals include all eleven hydrogen atoms of the empirical formula $\mathrm{C}_{11} H_{i j} \mathrm{NO}_{3}$ which implies seven double bond equivalents. $\mathrm{An}_{\mathrm{n}} A_{2} X_{2}$ system in the ${ }^{1} H$ NMR spectrum ( $\delta_{A}=2.77, \delta_{X}=3.49^{3} J_{A X}=7 \mathrm{~Hz}$ ) matching to two $\mathrm{CH}_{2}$ carbon signals in the ${ }^{13} \mathrm{C}$ NMR spectrum ( $\delta_{\mathrm{C}}=27.6$ and 47.8 ) indicates part structure A. A methyl signal in the ${ }^{l} H$ as well as in the ${ }^{13} \mathrm{C}$ NMR spectrum $\left(\delta_{H}=3.00\right.$, three protons according to the integral level, $\delta_{\mathrm{C}}=$ $34.8, J_{\mathrm{CH}}=137.3 \mathrm{~Hz}$ ) reveals an $N$-methyl group B. Two deshielded methylene protons with $\delta_{H}=$ 5.36 and one methylene carbon with $\delta_{\mathrm{C}}=101.3$ (triplet with $J_{\mathrm{CH}}=174.1 \mathrm{~Hz}$ ) reveal a methylenedioxy fragment (formaldehyde acetal) fragment $\mathbf{C}$. Two proton signals at $\delta_{H}=6.47$ and 7.39 without resolved proton-proton couplings and six carbon signals between $\delta_{\mathrm{C}}=106.7$ and 150.0, two with, four without ${ }^{l} J_{\mathrm{CH}}$ couplings, reveal a tetrasubstituted benzene ring $\mathbf{D}$ with two protons in $p$ position. One remaining carbonyl signal with $\delta_{\mathrm{C}}=164.2$ belongs to a carboxylic acid derivative function $\mathbf{E}$ in conjugation to a CC double bond, referring to the shielding of this signal relative to non-conjugated carboxylic acid derivatives ( $\delta_{\mathrm{C}}>170$ ).
34.83 .00

A

B

C

D

F

The carbon signal at $\delta_{\mathrm{C}}=133.4$ splits into a sextet with ${ }^{2} J_{\mathrm{CH}} \sim{ }^{3} J_{\mathrm{CH}}=6 \mathrm{~Hz}$. This carbon of the benzenoid ring $\mathbf{D}$ is therefore attached to part structure $\mathbf{A} ;{ }^{3} J_{\mathrm{CH}}$ coupling with one benzenoid proton in meta position, ${ }^{2} J_{\mathrm{CH}}$ coupling with methylene protons at $\delta_{A}=2.77,{ }^{3} J_{\mathrm{CH}}$ coupling with methylene protons at $\delta_{X}=3.49$ explains this; the resulting doublet of triplets of triplets collapses to a pseudosextet ("sxt") due to equal coupling constants. Because only one nitrogen atom appears in the empirical formula, substructure $\mathbf{A}, \mathbf{D}$ and $\mathbf{B}$ can be combined to an $N$-Methylphenylethylamine unit G. Substructures $\mathbf{A}-\mathbf{F}$ found so far by NMR include five of the seven double bond equivalents. Two remaining double bond equivalents are thus attributed to two additional rings. One ring is closed by the open ortho positions of the phenyl ring in $\mathbf{G}$ and the methylenedioxy function $\mathbf{C}$. The other arises from connection of the carboxy carbonyl with the remaining open bonds on the other side of the molecule, completing it to $N$-methyl-6,7-methylenedioxy-1-oxo-1,2,3,4-tetrahydroisoquinoline $\mathbf{H}$.

All carbon signals and resolved couplings can be assigned; C-6 is more deshielded ( $\delta_{C}=150.0$ ) than $\mathrm{C}-7\left(\delta_{\mathrm{C}}=146.5\right)$ due to electron withdrawal of the carboxy carbonyl group in para position.

## 27 Ethoxycarbonyl-4-(3-hydroxypropyl)-1-methylpyrrole

Here it is possible to consider how the starting materials may react and to check the result with the help of the spectra. Another approach would start by tabulating the ${ }^{13} \mathrm{C}$ shifts, CH multiplicities
and CH coupling constants and where possible the ${ }^{l} H$ shifts and the $H H$ coupling constants (Table 27.1). From this it is possible to identify those parts of the starting materials that have remained intact and those which have been lost and also those $H$ atoms which are linked to carbon and to heteroatoms.

Table 27.1. Interpretation of the NMR spectra in 27

|  | 10 | 22.5 | T | $\mathrm{CH}_{2}$ | 126.3 | 2.43 | $t$ | 7.0 |
|  | 11 | 14.2 | Q | $\mathrm{CH}_{3}$ | 126.7 | 1.26 | $t$ | 7.2 |
| CH partial formula |  |  |  | $\mathrm{C}_{11} \mathrm{H}_{16}$ |  |  |  |  |

This evaluation reveals that the three substructures of the reagents that are also present in the product include the $N$-methyl group (signals 8 ), the ethoxycarbonyl group (signals $1,7,11$ ) and the $n$ propyloxy group of the dihydro- 2 H -pyran ring (signals $6,9,10$ ). The ethyl ester $\mathrm{OCH}_{2}$ group can also be identified in the ${ }^{13} \mathrm{C}$ NMR spectrum because of its long-range quartet splitting ( 4.5 Hz ). The $H$ atom missing in the $\mathrm{C} H$ balance but present in the molecular formula appears in the ${ }^{l} H$ NMR spectrum as a broad $\mathrm{D}_{2} \mathrm{O}$-exchangeable signal ( $\delta_{H}=3.03$ ); since the compound only contains one nitrogen atom in the form of an $\mathrm{NCH}_{3}$ group, the signal at ( $\delta_{H}=3.03$ ) must belong to an OH group. Hence the dihydro- 2 H -pyran ring has opened.
By contrast, the aldehyde signals of the reagent 1 are missing from the NMR specira. Instead an $A B$ system appears in the ${ }^{l} H$ NMR spectrum $\left(\delta_{A}=6.52, \delta_{B}=6.73\right.$ with $J_{A B}=1.9 \mathrm{~Hz}$ ) whilst in the ${ }^{13} \mathrm{C}$ NMR spectrum two doublets appear $\left(\delta_{\mathrm{C}}=117.0\right.$ and 127.5 ) as well as two singlets ( $\delta_{\mathrm{C}}=121.9$ and 122.8), of which one doublet ( $\delta_{\mathrm{C}}=127.5$ ) is notable for the fact that it has a large CH coupling constant $\left(J_{\mathrm{CH}}=181.6 \mathrm{~Hz}\right.$ ). This value fits the $\alpha-\mathrm{C}$ atom of an enamine fragment (for the $\alpha-\mathrm{C}$ of an enol ether fragment $J_{C H} \geq 190 \mathrm{~Hz}$ would be expected). This leads to a 1,2,4-trisubstituted pyrrole ring 5, given the three double-bond equivalents (the fourth has already been assigned to the carboxy group), the $A B$ system in the ${ }^{i} H$ NMR spectrum ( $\delta_{A}=6.52, \delta_{B}=6.73$ ), the $N$-methyl group (signal 8) and the four ${ }^{13} \mathrm{C}$ signals in the $\mathrm{sp}^{2}$ shift range ( $\delta_{\mathrm{C}}=117-127.5$ ). The formation of the ring from reagents 1 and 2 via intermediates 3 and 4 can be inferred with no difficulty. All ${ }^{l} H$ and ${ }^{13} \mathrm{C}$ signals can be identified without further experiment by using their shift values, multiplicities and coupling constants.

## 28 p-Tolylsulphonyl-5-propylpyridine

The NMR spectra show that the product of the reaction contains:

- the propyl group $\mathbf{A}$ of 1-ethoxy-2-propylbuta-1,3-diene,

- the $p$-tolyl residue $\mathbf{B}$ from $p$-toluenesulphonyl cyanide.

- and (on the basis of their typical shift values and coupling constants, e.g. $J_{\mathrm{CH}}=180.2 \mathrm{~Hz}$ at $\delta_{\mathrm{C}}$ $=150.5$, a disubstituted pyridine ring $\mathbf{C}$ (three ${ }^{l} H$ signals in the ${ }^{I} H$ NMR, three $\mathrm{C} H$ doublets in the ${ }^{13} \mathrm{C}$ NMR spectrum) with substituents in the 2 - and 5 -positions, because in the ${ }^{1} H$ NMR spectrum the 8.2 Hz coupling $\left({ }^{3} J_{A M}={ }^{3} J_{3-H, 4-H}\right)$ appears instead of the 5 Hz coupling (Table 2.5 ).

However, the ethoxy group of 1 -ethoxy-2-propylbuta-1,3-diene is no longer present. Evidently the $p$-toluensulphonyl cyanide (2) undergoes [4+2] cycloaddition to l-ethoxy-2-propylbuta-1,3-diene (1). The resulting dihydropyridine 3 aromatises with 1,4-elimination of ethanol to form 2-p-tolyl-sulphonyl-5-propylpyridine (4).

Complete assignment is possible without further experiments using the characteristic shifts, multiplicities and coupling constants.

## 29 6-Methoxytetralin-1-one

Alnust all parts of the siruciure of this compound are already apparent in the ${ }^{\prime} H$ NMiR spectrum. It is possible to recognise:
E three methylenc groups linked to one another, $\mathbf{A}$,

- a methoxy group $\mathbf{B}$,
- and a $1,2,4$-trisubsituted benzene ring $\mathbf{C}$, in the following way:

The signal at $\delta_{H}=6.79$ splits into a doublet of doublets. The larger coupling $(8.7 \mathrm{~Hz})$ indicates a proton in the ortho position, the smaller $(2.5 \mathrm{~Hz})$ a further proton in a meta position, and in such a way that the ortho proton ( $\delta_{H}=7.97$ ) does not show any additional ortho coupling.

A

B

The ${ }^{13} \mathrm{C}$ NMR spectrum confirms

- three methylene groups $\mathbf{A}\left(\delta_{C}=23.6,30.3,39.1\right.$, triplets),
- the methoxy group $\mathbf{B}\left(\delta_{\mathrm{C}}=55.7\right.$, quartet),
- the trisubstituted benzene ring $\mathbf{C}$ (three CH doublets and three non-protonated C atoms between $\delta_{\mathrm{C}}=113.3$ and 164.6)
- and identifies additionally a keto-carbonyl group $\mathbf{D}$ at $\delta_{\mathrm{C}}=197.8$.

Five double-bond equivalents can be recognised from the shift values (four for the benzene ring and one for the carbonyl group). The sixth double-bond equivalent implied by the molecular formula belongs to another ring, so that the following pieces can be drawn for the molecular jigsaw puzzle:

B

A

The methoxy group is a $+M$ substituent, and so shields ortho protons and C atoms in ortho positions; the protons at $\delta_{H}=6.67$ and 6.79 reflect this shielding. The carbonyl group as a $-M$ substituent deshields ortho protons, and is ortho to the proton at $\delta_{H}=7.97$. With the additional doublebond equivalent for a ring, 6-methoxytetralin-1-one (E) results.
The difference between $2-\mathrm{CH}_{2}$ and $4-\mathrm{CH}_{2}$ is shown by the nuclear Overhauser enhancement (NOE) on the proton at $\delta_{H}=6.67$, if the methylene protons at $\delta_{H}=2.87$ are irradiated. The assignment of the methylene C atoms can be read from the CH COSY segment. The C atoms which are in close proximity to one another at $\delta_{\mathrm{C}}=113.3$ and 113.8 belong to $\mathrm{C}-5$ and $\mathrm{C}-7$. Carbon atom $\mathrm{C}-5$ is distinguished from $\mathrm{C}-7$ by the pseudo-quartet splitting ( ${ }^{3} J_{\mathrm{CH}}=3.4 \mathrm{~Hz}$ to $7-\mathrm{H}$ and $4-\mathrm{H}_{2}$ ) that involves the methylene group in the ortho position.

## 30 Triazolo[1,5-a]pyrimidine

Without comparative data on authentic samples, ${ }^{I} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR allow no differentiation between isomers 3 and 4 ; chemical shifts and coupling constants are consistent with either isomer.
${ }^{13} \mathrm{C}$ and ${ }^{1} \mathrm{H}$ chemical shifts $\delta_{\mathrm{C}}$ and $\delta_{H}$ (italic)

3

However, in ${ }^{15} \mathrm{~N}$ NMR spectra, the ${ }^{2} J_{\mathrm{NH}}$ coupling constants ( $\geq 10 \mathrm{~Hz}$ ) are valuable criteria for structure determination. The ${ }^{15} \mathrm{~N}$ NMR spectrum shows ${ }^{2} J_{\mathrm{N} H}$ doublets with $11.8,12.8$ and 15.7 Hz for all of the imino N atoms. Therefore, triazolo[1,5-a]pyrimidine (3) is present; for the [4,3-a] isomer 4, nitrogen atom $\mathrm{N}-1$ would appear as a singlet signal because it has no $H$ atoms at a distance of two bonds. This assignment of the ${ }^{15} \mathrm{~N}$ shifts is supported by a comparison with the spectra of derivatives which are substituted in positions 2 and $6^{8}$. If a substituent is in position 6 then the 1.5 Hz coupling is lost for $\mathrm{N}-4$; for substitution in position 2 or 6 a doublet instead of a triplet is obscrved for $\mathrm{N}-8$. The ${ }^{15} \mathrm{~N}$ shift and the ${ }^{2} J_{N H}$ coupling constants of $\mathrm{N}-1$ are considerably larger than for $\mathrm{N}-3$ as a result of the electronegativity of the neighbouring $\mathrm{N}-8$.

## 31 6-n-Butyltetrazolo[1,5-a]pyrimidine and 2-azido-5-n-butylpyrimidine

Tetrazolo[1,5-a]pyrimidine (1) exists in equilibrium with its valence isomer 2-azidopyrimidine (2).

In all types of NMR spectra ( ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C},{ }^{15} \mathrm{~N}$ ), 2-azidopyrimidine (2) can be distinguished by the symmetry of its pyrimidine ring (chemical equivalence of $4-\mathrm{H}$ and $6-\mathrm{H}, \mathrm{C}-4$ and $\mathrm{C}-6, \mathrm{~N}-1$ and $\mathrm{N}-3$ ) from tetrazolo $[1,5-a]$ pyrimidine (1) because the number of signals is reduced by one. Hence the prediction in Table 30.1 can be made about the number of resonances for the $n$-butyl derivative.

Table 30.1. The number of signals from 1 and 2 in the NMR spectra

| Compound | ${ }^{1} \mathrm{H}$ signals | Number of ${ }^{13} \mathrm{C}$ signals | ${ }^{15} \mathrm{~N}$ signals |
| :---: | :---: | :---: | :---: |
| 1 | 6 | 8 | 5 |
| 2 | 5 | 7 | 4 |

All of the NMR spectra indicate the predominance of the tetrazolo $[1,5-a]$ pyrimidine $I$ in the equilibrium by the larger intensity (larger integral) of almost all signals, although the non-equivalence of the outer $n$-butyl C atoms in both isomers (at $\delta_{\mathrm{C}}=22.5$ and 13.9 ) cannot be resolved in the ${ }^{13} \mathrm{C}$ NMR spectrum. By measuring the integrated intensities, for example, one obtains for the signals showing ${ }^{2} J_{\mathrm{NH}}$ splitting (of 12.0 and 11.5 Hz , respectively) recognisable signal pairs of the pyrimidine N atoms $\left(1\right.$, at $\delta_{\mathrm{N}}=275.6 ; 2$, at $\delta_{\mathrm{N}}=267.9$ ) of integrated intensities in the ratio 23 to 8.4 ( mm ). Since two $N$ nuclei generate the signal at $\delta_{N}=267.9$ because of the chemical equivalence of the ring N atoms in 2 its integral must be halved (4.2). Thus we obtain

$$
\% 2=100 \times 4.2 /(23+4.2)=15.4 \%
$$

The evaluation of other pairs of signals in the ${ }^{1} H$ and ${ }^{15} \mathrm{~N}$ NMR spectra leads to a mean value of $15.7 \pm 0.5 \%$ for 2 . Therefore, $6-n$-butyltetrazolo[1,5-a]pyrimidine ( 1 ) predominates in the equilibrium with $84.3 \pm 0.5 \%$.
Assignment of the signals is completed in Table 30.2. The criteria for assignment are the shift values (resonance effects on the electron density on C and N ), multiplicities and coupling constants. Because the difference between them is so small, the assignment of N-8 and N-9 is interchangeable.

Table 30.2. Assignment of the signals from 6-n-butyl tetrazolo[1,5-a]pyrimidine (1) and 2-azido-5-nbutylpyrimidine (2)

## 32 Hydroxyphthalide

The ' $H$ NMR spectrum does not show a signal for either a carboxylic acid or an aldehyde function. Instead, a $\mathrm{D}_{2} \mathrm{O}$-exchangeable signal indicates a less acidic OH proton ( $\delta_{H}=4.8$ ) and a nonexchangeable signal appears at $\delta_{H}=6.65$. The latter fits a CH fragment of an acetal or hemiacetal function which is strongly deshielded by two O atoms, also confirmed by a doublet at ( $\delta_{\mathrm{C}}=98.4$ with $J_{\mathrm{CH}}=174.6 \mathrm{~Hz}$ in the ${ }^{13} \mathrm{C}$ NMR spectrum. According to this it is not phthalaldehydic acid (1) but its acylal, hydroxyphthalide (2) .

The conclusive assignment of the ${ }^{l} H$ and ${ }^{13} \mathrm{C}$ signals of the ortho-disubstituted benzene ring at 80 and 20 MHz , respectively, encounters difficulties. However, the frequency dispersion is so good at 400 and 100 MHz , respectively, that the $H H$ COSY in combination with the CH COSY diagram allows a conclusive assignment to be made. Proton connectivities are derived from the $H H$ COSY; the CH correlations assign each of the four CH units. Both techniques converge to establish the CH skeleton of the ortho-disubstituted benzene ring.

Reference to the deshielding of a ring proton by an ortho carboxy group clarifies the assignment.

## 33 Dicyclopentadiene

The ${ }^{13} \mathrm{C}$ NMR spectrum does not show the three resonances expected for monomeric cyclopentadiene. Instead, ten distinct signals appear, of which the DEPT spectrum identifies four CH carbon
atoms in each of the shift ranges appropriate for alkanes and alkenes and in the alkane range additional two $\mathrm{CH}_{2}$ carbon atoms. This fits the [4+2]-cycloadduct 2 of cyclopentadiene 1 .

The structure of the dimer can be derived simply by evaluation of the cross signals in the $H H$ COSY plot. The cycloalkene protons form two $A B$ systems with such small shift differences that the cross signals lie within the contours of the diagonal signals.

${ }^{13} \mathrm{C}$ chemical shifts $\delta_{\mathrm{C}}$ assigned by HH and CH COSY

The complete assignment of the C atoms follows from the CH correlation ( CH COSY ) and removes any uncertainty concerning the ${ }^{13} \mathrm{C}$ signal assignments in the literature. The endo-linkage of the cyclopentene ring to the norbornene residue can be detected from the NOE on the protons at $\delta_{H}=2.66$ and 3.12, if the proton $7-H_{s y n}$ at $\delta_{H}=1.25$ is decoupled. Decoupling of the proton $7-H_{\text {anti }}$ at $\delta_{H}=1.47$ leads to NOE enhancement of only the bridgehead protons at $\delta_{H}=2.72$ and 2.80.

## 34 trans-1-Cyclopropyl-2-methylbuta-1,3-diene

In the ${ }^{13} \mathrm{C}$ NMR spectrum two signals with unusually small shift valucs $\left[\left(\mathrm{CH}_{2}\right)_{2}: \delta_{\mathrm{C}}=7.7 ; \mathrm{CH}: \delta_{\mathrm{C}}\right.$ $=10.6]$ and remarkably large CH coupling constants ( $J_{\mathrm{CH}}=161.9$ and 160.1 Hz ) indicate a monosubstituted cyclopropane ring $\mathbf{A}$. The protons which belong to this structural unit at $\delta_{H}=0.41$ $\left(A A^{\prime}\right), 0.82\left(B B^{\prime}\right)$ and $1.60(M)$ with typical values for cis couplings ( 8.1 Hz ) and trans couplings $(4.9 \mathrm{~Hz})$ of the cyclopropane protons can be identified from the CH COSY plot.

The additional coupling ( 9.8 Hz ) of the cyclopropane proton $X$ at $\delta_{H}=1.60$ is the result of a vicinal $H$ atom in the side-chain. This contains a methyl group $\mathbf{B}$, a vinyl group $\mathbf{C}$ and an additional substituted ethenyl group $\mathbf{D}$, as may be seen from the one dimensional ${ }^{l} H$ and ${ }^{13} \mathrm{C}$ NMR spectra and from the CH COSY diagram.

B

C

Since the vinyl-CH proton at ( $\delta_{H}=6.33$ shows no additional ${ }^{3} J_{H H}$ couplings apart from the doublet of doublets splitting (cis and trans coupling), the side-chain is a 1-isoprenyl chain $\mathbf{E}$ and not a 1-methylbuta-1,3-dienyl residue F.

Hence it must be either trans- or cis-1-cyclopropyl-2-methylbuta-1,3-diene (1-isoprenylcyclopropane), $\mathbf{G}$ or $\mathbf{H}$.

In decoupling the methyl protons, the NOE difference spectrum shows a nuclear Overhauser enhancement on the cyclopropane proton at $\delta_{H}=1.60$ and on the terminal vinyl proton with trans coupling at $\delta_{H}=5.05$ and, because of the geminal coupling, a negative NOF on the other terminal proton at $\delta_{H}=4.87$. This confirms the trans configuration $\mathbf{G}$. In the cis isomer $\mathbf{H}$ no NOE would be expected for the cyclopropane proton, but one would be expected for the alkenyl- $H$ in the $\alpha$ position indicated by arrows in $\mathbf{H}$.

HH multiplicities, HH coupling constants $(\mathrm{Hz})$, coupling protons

## 35 cis-6-Hydroxy-1-methyl-4-isopropylcyclohexene (carveol)

The correlation signals of the INADEQUATE experiment directly build up the ring skeleton $\mathbf{A}$ of the compound. Here characteristic ${ }^{13} \mathrm{C}$ shifts $\left(\delta_{\mathrm{C}}=123.1,137.6 ; 148.9,109.1\right)$ establish the existence and position of two double bonds and of one tetrahedral $\mathrm{C}-\mathrm{O}$ single bond ( $\delta_{\mathrm{C}}=70.5$ ). DEPT spectra for the analysis of the CH multiplicities become unnecessary, because the INADEQUATE plot itself gives the number of CC bonds that radiate from each C atom.
The CH connectivities can be read off from the CH COSY plot; thus the complete pattern $\mathbf{B}$ of all $H$ atoms of the molecule is established. At the same time an $\mathrm{O} H$ group can be identified by the fact that there is no correlation for the broad signal at $\delta_{H}=4.45$ in the CH COSY plot.

* AB systems : a for axial, e for equatorial protons

The relative configuration of the OH and isopropenyl groups remains to be established. The ${ }^{l} H$ signal at $\delta_{H}=1.55$, a $\mathrm{CH}_{2}$ proton, splits into a pseudotriplet ( 12.4 Hz ) of doublets ( 10.1 Hz ). One of the two 12.4 Hz couplings is the result of the other geminal proton of the $\mathrm{CH}_{2}$ group; the second of the two 12.4 Hz couplings and the additional 10.1 Hz coupling correspond to an antiperiplanar relationship of the coupling protons; the vicinal coupling partners of this methylene proton are thus located axial as depicted in the stereoformula $\mathbf{C}$, with a cis configuration of the OH and isopropenyl groups. Hence it must be one of the enantiomers of carveol $(\mathbf{C})$ shown in projection $\mathbf{D}$.

C

$\equiv$

D

## 36 trans-2-Methylcyclopentanol

Following the strategy applied in the previous problem, the correlation signals of the INADEQUATE experiment build up the methylcyclopentane skeleton A of the compound. DEPT subspectra c support the analysis of the CH multiplicities also resulting from the INADEQUATE plot which gives the number of CC bonds that radiate from each C atom.
Proton signals are assigned in $\mathbf{B}$ by means of the CH connectivities which can be read off from the CH COSY plot. Additionally, an OH group can be identified by the fact that there is no correlation for the broad signal at $\delta_{H}=4.33$ in the CH COSY plot. Connection of the OH group ( $\delta_{H}=4.33$ )
with the deshielded CH carbon atom ( $\delta_{\mathrm{C}}=79.2$ ) completes the structure of 2-methylcyclopentanol.

A

B

Signal overcrowding prevents an analysis of multiplets and coupling constants in the proton NMR spectrum so that the relative configuration is better derived from NOE difference spectra e. Decoupling of the methyl protons $\left(\delta_{H}=0.74\right)$ leads to a significant NOE at the vicinal CH proton $\left(\delta_{H}=3.43\right)$ and vice versa. The methyl protons and the CH proton are cis to each other; consequently, hydroxy function and methyl group adopt the trans configuration $\mathbf{C}$ (two enantiomers).

## 37 trans-2-(2-Pyridyl)methylcyclohexanol

The CH fragment which is linked to the OH group ( $\delta_{H}=5.45$ ) can easily be located in the ${ }^{l} H$ and ${ }^{13} \mathrm{C}$ NMR spectra. The chemical shift values $\delta_{C}=74.2$ for C and $\delta_{H}=3.16$ for $H$ are read from the CH COSY plot. The ${ }^{l} H$ signal at $\delta_{I I}=3.16$ splits into a triplet $(11.0 \mathrm{~Hz})$ of doublets $(4.0 \mathrm{~Hz})$. The fact hat an antiperiplanar coupling of 11 Hz appears twice indicates the diequatorial configuration (trans) of the two substituents on the cyclohexane ring 3. If the substituents were positioned equatorial-axial as in 4 or 5 , then a synclinal coupling of ca 4 Hz would be observed two or threc times.

1

2
$+\mathrm{H}_{2} \mathrm{O}$
$-\mathrm{LiOH}$

3

4

5

The pyridine chemical shifts can easily be assigned with the help of the $H H$ coupling constants (cf. 3-acetylpyridine, Problem 6). The ${ }^{13} \mathrm{C}$ chemical shift values of the bonded C atoms can then be read from the CH COSY plot. It is more difficult to assign the tetramethylene fragment of the cyclohexane ring because of signal overcrowding. The geminal $A B$ systems of the individual $\mathrm{CH}_{2}$ groups are clearly differentiated in the CH COSY plot; the axial protons ( $\delta_{H}=1.01-1.22$ ) show smaller ${ }^{l} H$ shift values than their equatorial coupling partners on the same C atom as a result of anisotropic effects; they also show pseudoquartets because of two additional diaxial couplings. The $H H$ COSY plot identifies the $H H$ connectivities of the $H$ atoms attached to the C-7-C-2 and C-1-C-6 subunits for structure 3. Finally, the INADEQUATE plot differentiates between the $\mathrm{CH}_{2}$ groups in positions 4 and 5 of the cyclohexane ring and confirms the aliphatic carbon skeleton.

7- $H^{A} H^{B}$ form an $A B$ system ( ${ }^{2} J_{A B}=14 \mathrm{~Hz}$ ) of doublets $\left(H^{A}:{ }^{3} J=5.0 ; H^{B}:{ }^{3} J=4.5 \mathrm{~Hz}\right)$ as a result of coupling with $2-H$.

## 38 Nona-2-trans-6-cis-dienal

From the $H H$ COSY plot the following $H H$ connectivities $\mathbf{A}$ are derived:
$\begin{array}{llllllllllll}\text { A } & 0.92 & -1.99 & 5.39 & -5.26 & -2.22 & -2.36 & -6.80 & 6.08 & -9.45 & \delta_{H}\end{array}$
In the CH COSY plot it can be established which C atoms are linked with these protons; thus the $\mathbf{C H}$ skeleton $\mathbf{B}$ can readily be derived from $\mathbf{A}$ :

B

Structural elucidation can be completed to give $\mathbf{C}$ if the CH multiplicities from the ${ }^{13} \mathrm{C}$ NMR spectrum and characteristic chemical shift values from the ${ }^{1} H$ and ${ }^{13} \mathrm{C}$ NMR spectra are also taken into account. The CH bond with $\delta_{\mathrm{C}} / \delta_{H}=194.0 / 9.45$, for example, clearly identifies an aldehyde group; CH bonds with $\delta_{\mathrm{C}} / \delta_{H}=133.2 / 6.08,158.1 / 6.80,126.7 / 5.26$ and 133.5/5.39 identify two CC double bonds of which one ( $\delta_{\mathrm{C}} / \delta_{H}=133.1 / 6.08$ and $158.1 / 6.80$ ) is polarised by the $-M$ effect of the aldehyde group.

## C

Hence the compound is nona-2,6-dienal. The relative configuration of both CC double bonds follows from the $H H$ coupling constants of the alkene protons in the ${ }^{l} H$ NMR spectrum. The protons of the polarised 2,3-double bond are in trans positions ( ${ }^{3} J_{H H}=15.5 \mathrm{~Hz}$ ) and those on the 6,7double bond are in cis positions ( ${ }^{3} J_{H H}=10.5 \mathrm{~Hz}$ ). The structure is therefore nona-2-trans-6-cisdienal, D.
In assigning all shift values, CH and $H H$ coupling constants, differentiation between $\mathrm{C}-2$ and $\mathrm{C}-7$ is at first difficult because the signals are too crowded in the ${ }^{13} \mathrm{C}$ NMR spectrum. Differentiation is possible, however, on closer examination of the CH COSY plot and the coupled ${ }^{13} \mathrm{C}$ NMR spectrum: the signal at $\delta_{\mathrm{C}}=133.2$ splits as a result of CH long-range couplings into a doublet ( 25.0 Hz ) of triplets ( 5.7 Hz ), whose 'left' halves overlap in each case with the less clearly resolved longrange multiplets of the neighbouring signal, as the signal intensities show. Thereby, the coupling constant of 25.0 Hz locates the aldehyde proton which is two bonds apart from the C atom at $\delta_{\mathrm{C}}=$ 133.2.

## 39 2,3-Diaza-7,8,12,13,17,18-hexaethylporphyrin

The ${ }^{l} H$ NMR spectrum displays signals of shielded protons ( $\delta_{H}=-2.35$, integral level 1) and of deshielded ones ( $\delta_{H}=10.45$ and 9.39 , integral levels $1: 1$ ). This reflects a ring current due to aromaticity as described for annulenes and porphyrins in section 2.5.2. To conclude, the reaction involves an oxidative cyclisation of 2,5 -bis( 2 -pyrrolylmethyl)-1 H -pyrrole 2 with 4 H -triazole-3,5dialdehyde 3 to the corresponding 2,3-diazaporphyrin 4, following the " $3+1$ " pathway of porphyrin synthesis. Two non-equivalent tautomers may exist; these are the diaza[18]annulene $4 a$ and the tetraaza[18] annulene $\mathbf{4 b}$.
Carbon atoms and protons are assigned by means of the proton-carbon connectivities as identified in the HC HSQC and HMBC experiment (b and $\mathbf{c}$ ). The latter also permits the derivation of the connection of the ethyl groups to the porphyrin ring. The cross signals in the relevant part a of the HH COSY plot (a) are used to connect the methyl and methylene subunits to the ethyl groups.
3

2

The equivalence of the inner NH protons $\left(\delta_{H}=-2.35\right)$ as well as correlation signals with the pyrrolic carbons only ( $\delta_{\mathrm{C}}=143.8,141.6,139.8$ and 136.7) provide evidence for the diaza[18]annulene tautomer $4 a$. Two separate $\mathrm{N} H$ proton signals and cross signals with the $\alpha$-carbon atoms ( $\delta_{\mathrm{C}}=159.3$ ) of the triazole ring are expected, in contrast, for the tetraaza[18]annulene tautomer $4 b$.

## 40 2-Hydroxy-3,4,3',4'-tetramethoxydeoxybenzoin

First, nine double-bond equivalents from the molecular formula, iwelve signals in the shift range appropriate for benzenoid C atoms and five multiplets in the shift range appropriate for benzenoid protons, with typical aromatic coupling constants, all indicate a double bond and two benzene rings. Of these two rings, one is 1,2,3,4-tetrasubstituted ( $A B$ system at $\delta_{H}=6.68$ and 7.87 with an ortho coupling of 9 Hz ); the other is $1,2,4$-trisubstituted ( $A B C$ system at $\delta_{H}=6.79,6.87$ and 6.97 with ortho and meta coupling, 8 and 2 Hz , respectively). Substituents indicated include:

- in the ${ }^{l} H$ NMR spectrum a phenolic OH group $\left(\delta_{H}=12.34\right)$,
- in the ${ }^{13} \mathrm{C}$ NMR spectrum a ketonic carbonyl function $\left(\delta_{\mathrm{C}}=203.7\right)$
- and in both spectra four methoxy groups ( $\delta_{H}=3.68,3.70,3.71,3.87$, and $\delta_{\mathrm{C}}=55.7,56.3$, 60.1 , respectively), in addition to a methylene unit ( $\delta_{H}=4.26$ and $\delta_{\mathrm{C}}=44.3$, respectively).

In order to derive the complete structure, the connectivities found in the CH COSY and CH CO LOC plots are shown in Table 40.1.

Table 40.1. Proton-Carbon $\left(J_{C H}\right)$ connectivities from the CH COSY and CH COLOC plots

| Partial structure | Proton | carbon atom attached | carbon atoms in two or three (or four) bonds distance $\delta_{c}$ |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\delta_{H}$ | $\delta_{c}$ |  |  |  |  |
| A | 7.87 | 128.0 | 203.7 | 158.6 | 156.5 |  |
| B | 6.68 | 104.0 | 136.0 | 114.5 |  |  |
| C | 6.91 | 113.6 | 147.9 | 121.6 | 44.3 |  |
| D | 6.87 | 112.0 | 148.9 | 127.5 |  |  |
| E | 6.79 | 121.6 | 147.9 | 113.6 |  |  |
| F | 4.26 | 44.3 | 203.7 | 127.5 | 121.6 | 113.6 |
| A | 3.87 | 56.3 | 158.6 |  |  |  |
| D | 3.71 | 55.7 | 148.9 |  |  |  |
| C | 3.70 | 55.7 | 147.9 |  |  |  |
| B | 3.68 | 60.1 | 136.0 |  |  |  |

For the 1,2,3,4-tetrasubstituted benzene ring the partial structures $\mathbf{A}$ and $\mathbf{B}$ are derived from Table 40.1 from the connectivities of the $A B$ protons at $\delta_{H}=6.68$ and $\delta_{H}=7.87$ and the methoxy protons at $\delta_{H}=3.68$ and 3.87. The complete arrangement of the C atoms of the second $1,2,4$-trisubstituted benzene ring can be derived from the connectivities $\mathbf{C}, \mathbf{D}$ and $\mathbf{E}$ of the protons of the $A B C$ system ( $\delta_{H}=6.79,6.87$ and 6.97 ). From the partially resolved contours of the overlapping corrclation signals at $\delta_{\mathrm{C}} / \delta_{H}=148.9 / 3.71$ and $147.9 / 3.70$, the methoxy protons at $\delta_{H}=3.70$ and 3.71 can be attached to methoxy carbon atoms with the common ${ }^{13} \mathrm{C}$ signal at $\delta_{\mathrm{C}}=55.7$.

Finally, from the partial structures $\mathbf{A}$ and $\mathbf{F}$ it can be seen that the two benzene rings are linked to one another by a $-\mathrm{CO}-\mathrm{CH}_{2}-$ unit $\left(\delta_{\mathrm{C}} / \delta_{H}=203.744 .3 / 4.26\right)$. Hence it must bc 2 -hydroxy- $3,4-$ 3',4'-tetramethoxydeoxybenzoin, $\mathbf{G}$.

## $413{ }^{\prime}, 4$ ',7,8-Tetramethoxyisoflavone

The molecular formula contains ten double-bond equivalents. In the ${ }^{1} H$ and ${ }^{13} \mathrm{C}$ NMR spectra four methoxy groups can be identified ( $\delta_{\mathrm{C}}=61.2,56.7,57.8$ and $\delta_{H}=3.96,3.87,3.78$, respectively). Of these, two have identical frequencies, as the signal intensity shows ( $\delta_{\mathrm{C}}=55.8$ and $\delta_{H}=3.78$ ). In the ${ }^{I} H$ NMR spectrum an $A B$ system ( $\delta_{H}=7.29$ and 7.85 ) with ortho coupling ( 9 Hz ) indicates a 1,2,3,4-tetrasubstituted benzene ring $\mathbf{A}$; an additional $A B C$ system $\left(\delta_{H}=6.99,7.12\right.$ and 7.19) with ortho and meta coupling ( 8.5 and 2 Hz ) belongs to a second 1,2,4-trisubstituted benzene ring B. What is more, the ${ }^{13} \mathrm{C}$ NMR spectrum shows a conjugated carbonyl C atom $\left(\delta_{\mathrm{C}}=175.1\right)$ and a considerably deshielded CH fragment $\left(\delta_{\mathrm{C}}=154.0\right.$ and $\left.\delta_{H}=8.48\right)$ with the larger $\mathrm{C} H$ coupling $(198.2 \mathrm{~Hz})$ indicative of an enol ether bond, e.g. in a heterocycle such as furan, $4 H$-chromene or chromone $\mathbf{C}$.

Knowing the substitution pattern of both benzene rings $\mathbf{A}$ and $\mathbf{B}$, one can deduce the molecular structure from the CH connectivities of the CH COSY and CH COLOC plots. The interpretation of both experiments leads firstly to the correlation Table 41.1.

Table 41.1. Proton-Carbon $\left(J_{C H}\right)$ connectivities from the $\mathrm{CH} C O S Y$ and CH COLOC plots

| Partial structure | Proton | carbon atom attached | carbon atoms in two or three (or four) bonds distance |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\delta_{H}$ | $\delta_{C}$ |  | $\delta_{c}$ |  |
| C | 8.48 | 154.0 | 175.1 | 150.1 | 123.3 |
| A | 7.85 | 121.2 | 175.1 | 156.4 | 150.1 |
| A | 7.29 | 111.2 | 136.3 | 118.7 |  |
| B | 7.19 | 112.9 | 148.9 | 121.5 |  |
| B | 7.12 | 121.5 | 148.9 |  |  |
| B | 6.00 | 111.8 | 148.5 | 124.5 |  |
| A | 3.96 | 56.7 | 156.4 |  |  |
| A | 3.87 | 61.2 | 136.3 |  |  |
| R | 3.78 | 55.8 | 148.0 | 148.5 |  |

The benzene rings $\mathbf{A}$ and $\mathbf{B}$ derived from the ${ }^{1} H$ NiviR spectrum can be completed using Table 41.1. The way in which the enol ether is bonded is indicated by the correlation signal of the proton at $\delta_{I I}=8.48$. The structural fragment $\mathbf{C}$ results, incorporating the C atom resonating at $\delta_{\mathrm{C}}=123.3$, which has not been accommodated in ring $\mathbf{A}$ or $\mathbf{B}$ and which is two bonds $\left({ }^{2} J_{C H}\right)$ removed from the enol ether proton.

The combination of the fragments A-C completes the structure and shows the compound to be $3^{\prime}, 4^{\prime}, 7,8$-tetramethoxyisoflavone, D.

## 42 3',4',6,7-Tetramethoxy-3-phenyIcoumarin

Isoflavones 3 that are unsubstituted in the 2-position are characterised in their ${ }^{l} H$ and ${ }^{13} \mathrm{C}$ NMR spectra by two features:

- a carbonyl-C atom at $\delta_{\mathrm{C}} \sim 175$ (cf. problem 41);
- an enol ether $\mathrm{C} H$ fragment with high ${ }^{1} H$ and ${ }^{13} \mathrm{C}$ chemical shift values ( $\delta_{H} / \delta_{\mathrm{C}} \sim 8.5 / 154$ ) and a remarkably large ${ }^{\prime} J_{C I I}$ coupling constant ( $\sim 198 \mathrm{~Hz}$, cf. problem 41).

The NMR spectra of the product do not show these features. The highest ${ }^{13} \mathrm{C}$ shift value is $\delta_{\mathrm{C}}=$ 160.9 and indicates a conjugated carboxy-C atom instead of the keto carbonyl function of an isoflavone ( $\delta_{\mathrm{C}}=175$ ). On the other hand, a deshieided CH fragment at $\delta_{\mathrm{C}} / \delta_{H}=138.7 / 7.62$ appears in the ${ }^{13} \mathrm{C}$ NMR spectrum, which belongs to a CC double bond polarised by a $-M$ effect. The two together point to a coumarin 4 with the substitution pattern defined by the reagents.

The correlation signals of the CH COSY and the CH COLOC plots (shown in the same diagram) confirm the coumarin structure 4 . The carbon and hydrogen chemical shifts and couplings indicated in Table 42.1 characterise rings $\mathbf{A}, \mathbf{B}$ and $\mathbf{C}$. The connection of the methoxy protons also follows easily from this experiment. The assignment of the methoxy C atoms remains unclear because their correlation signals overlap. Hence the correspondence between the methoxy double signal
at $\delta_{C}=55.8$ and the $3^{\prime}, 4^{\prime}$-methoxy signals $\left(\delta_{C}=55.8\right)$ of $3^{\prime}, 4^{\prime}, 6,7$-tetramethoxyisoflavone (problem 41) may be useful until experimental proof of an alternative is found.

Table 42.1. Proton-carbon $\left(J_{\mathrm{CH}}\right)$ connectivities from the CH COSY and CH COLOC plots

| $\begin{aligned} & \text { Partial } \\ & \text { structure } \end{aligned}$ | Proton | carbon atom attached | carbon atoms in two or three (or four) bonds distance |  |  |  |

${ }^{13} \mathrm{C}$ and ${ }^{1} H$ chemical shifts $\delta_{\mathrm{C}}$ and $\delta_{H}$ (talic)

CH multiplicities, CH coupling constants ( Hz ) , coupling protons

## 43 Aflatoxin $B_{1}$

The keto-carbonyl ${ }^{13} \mathrm{C}$ signal at $\delta_{\mathrm{C}}=200.9$ would only fit the aflatoxins $\mathrm{B}_{1}$ and $\mathrm{M}_{\mathrm{l}}$. In the ${ }^{13} \mathrm{C}$ NMR spectrum an enol ether- $\mathrm{C} H$ fragment can also be recognised from the chemical shift value of $\delta_{\mathrm{C}}=145.8$ and the typical one-bond coupling constant $J_{\mathrm{CH}}=196 \mathrm{~Hz}$; the proton involved appears at $\delta_{H}=6.72$, as the CH COSY plot shows. The ${ }^{l} H$ triplet which belongs to it overlaps with a sing-
let, identified by the considerable increase in intensity of the central component. The coupling constant of the triplet 2.5 Hz is repeated at $\delta_{H}=5.39$ and 4.24. Judging from the CH COSY plot, the proton at $\delta_{H}=5.39$ is linked to the C atom at $\delta_{\mathrm{C}}=102.5$ (Table 43.1); likewise, on the basis of its shift value it belongs to the $\beta-C$ atom of an enol ether fragment, shielded by the $+M$ effect of the enol ether O atom. The other coupling partner, the allylic proton at $\delta_{H}=4.24$, is linked to the C atom at $\delta_{\mathrm{C}}=47.1$, as can be seen from the CH COSY plot (Table 43.1). It appears as a doublet ( 7 Hz ) of pseudotriplets ( 2.5 Hz ). The larger coupling constant ( 7 Hz ) reoccurs in the doublet at $\delta_{H}=6.92$. According to the CH COSY plot (Table 43.1) the C atom at $\delta_{\mathrm{C}}=113.5$ is bonded to this proton. Hence the evidence tends towards partial structure $\mathbf{A}$, and so away from aflatoxin $\mathrm{M}_{1}$, in which the allylic proton would be substituted by an OH group.

| A | 4.24 | 47.1 |  |  |  |
| A | 5.39 | 102.5 | 145.8 |  |  |
| A | 6.72 | 145.8 | 113.5 | 102.5 | 47.1 |
| B | 6.72 | 91.4 | 165.1 | 161.4 | 107.2 |
| A | 6.92 | 113.5 |  |  | 103.5 |

Further interpretation of the CH COSY / CH COLOC plots allows additional assignments to be made for tragments $\mathbf{B}$ and $\mathbf{C}$ of atlatoxin $\mathrm{B}_{1}$.
B

$C$

Since fragment $\mathbf{A}$ was clearly assigned with the help of $H H$ coupling constants, all of the C atoms not included in $\mathbf{A}$, which, according to the CH COLOC plot, are two or three bonds apart from the equivalent protons at $\delta_{H}=6.72$ (Table 43.1), belong to the benzene ring $\mathbf{B}$.
The assignment of the quaternary C atoms at $\delta_{\mathrm{C}}=154.3,152.1$ and 116.4 has yet to be established. The signal with the smallest shift $\left(\delta_{\mathrm{C}}=116.4\right)$ is assigned to $\mathrm{C}-11$ a because the substituent effects of carboxy groups on $\alpha$-C atoms are small. Since the signal at $\delta_{C}=152.1$ in the coupled spectrum displays a splitting ( ${ }^{3} J_{C H}$ coupling to $9 \mathrm{a}-\mathrm{H}$ ), it is assigned to $\mathrm{C}-3 \mathrm{c}$.

Additional evidence for the assignment of the other C atoms is supplied by the CH coupling constants in the Table shown.

## 44 1,5-Dimethylcyclohexa-1,3-dien-5-ol-6-one, dimer

The ${ }^{13} \mathrm{C}$ NMR spectrum of the metabolite shows 16 signals instead of 8 as expected from the elemental composition determined by high-resolution mass spectrometry. Moreover, aromaticity of the 2,6-xylenol is obviously lost after metabolism because two ketonic carbonyl carbon atoms ( $\delta_{\mathrm{C}}$ $=203.1$ and 214.4) and four instead of twelve carbon signals are observed in the shift range of trigonal carbon nuclei ( $\delta_{\mathrm{C}}=133.1,135.4,135.6$ and 139.4) in the ${ }^{13} \mathrm{C}$ NMR spectra. To conclude, metabolism involves oxidation of the benzenoid ring.
The connectivities found in the $H H$ COSY diagram reveal two partial stuctures $\mathbf{A}$ and $\mathbf{B}$ according to Table 44.1. These are supported by the identical proton-proton coupling constants of the coupling protons.

Table 44.1. Proton-proton $\left(J_{H H}\right)$ connectivities and partial structures $\mathbf{A}$ and $\mathbf{B}$ from the HH COSY plots

A

B

Carbon-proton bonds are then assigned by means of the one-bond CH connectivities observed in the CH COSY diagram (Table 44.2). This completes partial structures $\mathbf{A}$ and $\mathbf{B}$ to the $\mathrm{C} H$ skeletons $\mathbf{C}$ and $\mathbf{D}$.

C

D

Table 44.2. Proton-carbon $\left(J_{C H}\right)$ connectivities from the CH COSY and CH COLOC plots

| $\mathrm{CH}_{n}$ | Proton | carbon atom <br> attached <br> $\delta$ | carbon a tom s <br> in two or three bonds distance <br> $\delta_{\mathrm{C}}$ |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| CH | $\delta_{\mathrm{H}}$ | 6.28 | 139.4 |  |  |
| CH | 6.22 | 135.4 |  |  |  |
| CH | 5.44 | 133.1 |  |  |  |
| CH | 3.33 | 44.5 |  |  |  |
| CH | 3.22 | 42.7 |  |  |  |
| CH | 2.85 | 43.4 |  |  |  |
| $\mathrm{CH}_{3}$ | 1.79 | 16.3 | 203.1 | 139.4 | 135.6 |
| $\mathrm{CH}_{3}$ | 1.28 | 15.7 | 214.4 | 133.1 | 53.7 |
| $\mathrm{CH}_{3}$ | 1.26 | 31.7 | 203.1 | 73.7 | 42.7 |
| $\mathrm{CH}_{3}$ | 1.17 | 26.1 | 214.4 | 72.6 |  |

Two- and three-bond CH connectivities of the methyl protons detected in the CH COLOC diagram identify the partial structures $\mathbf{E}$ and $\mathbf{F}$. Only one bond from $\delta_{\mathrm{C}}=72.6$ to $\delta_{\mathrm{C}}=44.5$ could not be directly identified because of the absence of the corresponding cross signal ( $\delta_{H}=1.17$ with $\delta_{\mathrm{C}}$ $=44.5$ ). Nevertheless, partial structure $\mathbf{E}$ is reasonable, assuming the six-membered ring to be retained during metabolism.

E

Fragments $\mathbf{E}$ and $\mathbf{F}$ which include all 16 carbon atoms detected by ${ }^{13} \mathrm{C}$ NMR can be attached to each other in two ways $\mathbf{G}$ or $\mathbf{H}$; the structure $\mathbf{G}$ is realised, as follows from the NOE difference specira, which show a significant NOE between the methyl protons at $\delta_{H}=I .28$ and the alkene proton at $\delta_{H}=6.28$ and vice versa (Table 44.3).

G

H

Table 44.3. Significant proton-proton NOEs from the HH NOE difference spectra

| $\delta_{H}$ | 6.28 | 6.22 | 5.4 | 3.33 | 3.22 |  |  |  |  | 1.17 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 6.28 | - |  |  |  |  | + | + | + |  |  |
| 6.22 |  | - | + | + |  |  |  |  |  | + |
| 5.44 |  | + | - |  |  |  |  | + |  |  |
| 3.33 |  | + |  | - | + |  |  |  |  | + |
| 3.22 |  |  |  | + | - | + |  |  | + |  |
| 2.85 | + |  |  |  | + | - |  | + |  |  |
| 1.79 | $+$ |  |  |  |  |  | - |  |  |  |
| 1.28 | $+$ |  | + |  |  | + |  | - |  |  |
| 1.26 |  |  |  |  | + |  |  |  | - |  |
| 1.17 |  | + |  | + |  |  |  |  |  | - |

An NOE between the the alkene proton at $\delta_{H}=6.22$ and the methyl protons at $\delta_{H}=1.17$ establishes the relative configuration (exo) of the respective methyl group. The exo attachment of the six-membered ring in the stereostructure I follows, in particular, from the NOE between the methyl protons at $\delta_{H}=1.26$ and the bridgehead proton at $\delta_{H}=3.22$ as well as the absence of effects between the alkenyl proton pair with $\delta_{H}=5.44 / 6.22$ and the bridgehead proton pair with $\delta_{H}=$ 2.85/3.22.

Also the mirror image of the structure I, correctly denoted as exo-3,10-dihydroxy-3,5,8,10-tetramethyltricyclo $\left[6,7,70^{2,7}\right]$ dodeca- 5,11 -diene- 4,9 -dione, would be possible since enantiomers are not differentiated by NMR. A retro-Diels-Alder fragmentation of I to $\mathrm{C}_{8} \mathrm{H}_{10} \mathrm{O}_{4}$ explains why the molecular ion corresponding to the molecular formula $\mathrm{C}_{16} \mathrm{H}_{20} \mathrm{O}_{4}$ is not detected in the mass spectrum. The metabolite I could be formed by Diels-Alder dimerisation of 1,5-dimethylcyclohexa-1,3-dien-5-ol-6-one $\mathbf{J}$ as the primary metabolite which acts as diene and dienophile as well ${ }^{39}$.

## 45 Asperuloside

The molecular formula $\mathrm{C}_{18} \mathrm{H}_{22} \mathrm{O}_{11}$ contains eight double-bond equivalents, i.e. four more than those in the framework 1 known to be present. The ${ }^{13} \mathrm{C}$ NMR spectrum shows two carboxy-CO
double bonds ( $\delta_{\mathrm{C}}=170.2$ and 169.8) and, apart from the enol ether fragment $\left(\mathrm{C}-3: \delta_{\mathrm{C}}=148.9, J_{\mathrm{CH}}\right.$ $=194.9 \mathrm{~Hz} ; \mathrm{C}-4: \delta_{\mathrm{C}}=104.8,+M$ effect of the ring O atom), a further CC double bond ( $\mathrm{C}: \delta_{\mathrm{C}}=142.9$; $\mathrm{CH}: \delta_{\mathrm{C}}=127.3$ ); the remaining double-bond equivalent therefore belongs to an additional ring.
Analysis of the CH correlation signals ( CH COSY/CH COLOC) for the protons at $\delta_{H}=7.38$ and 5.54 (Table 45.1 ) shows this ring to be a five-membered lactone. The CH correlation signals with the protons at $\delta_{H}=4.65$ ( $A B$ system of methylene protons on $\mathrm{C}-10$ ) and $\delta_{H}=2.04$ (methyl group) identify and locate an acetate residue ( $\mathrm{CO}: \delta_{\mathrm{C}}=170.2 ; \mathrm{CH}_{3}: \delta_{\mathrm{C}}=20.8$ ) at $\mathrm{C}-10$ (Table 45.1).

Table 45.1. Partial structures from the CH COSY and CH COLOC plots (the protons are given in italic numerals, C atoms separated by a single bond are given in bold numerals and C atoms separated by two or three bonds are given in small ordinary numerals

CH correlation maxima with the hydrogen atoms at $\delta_{H}=5.70,5.54,4.65,3.55$ and 3.22 finally establish the position of the additional CC double bond (C- 7/C-8, Table 45.1). Hence the basic structure $\mathbf{A}$ of the aglycone is now clear.

The iridoid monoterpenoid part of the structure C-1-C-9-C-5-C-6-C-7 (B) is confirmed by the HH COSY plot:

The ${ }^{l} H$ and ${ }^{13} \mathrm{C}$ signal assignments of glucopyranoside ring $\mathbf{C}$ are derived from the $H H \mathrm{COSY}$ and CH COSY diagram:

As can be seen from a Dreiding model, the five- and six-membered rings of A only link cis so that a bowl-shaped rigid fused-ring system results. Protons $5-\mathrm{H}, 6-\mathrm{H}$ and $9-\mathrm{H}$ are in cis positions and therefore almost eclipsed. The relative configuration at C-1 and C-9 has yet to be established. Since $1-H$ shows only a very small ${ }^{3} J_{H H}$ coupling ( 1.5 Hz ) which is scarcely resolved for the coupling partner $9-H\left(\delta_{H}=3.22\right)$, the protons are located in such a way that their CH bonds enclose a dihedral angle of about $120^{\circ}$. The O -glucosyl bond is therefore positioned synclinal with respect to $9-\mathrm{H}$. The antiperiplanar coupling constant ( 8 Hz ) of the protons $1^{\prime}-H\left(\delta_{H}=4.49\right)$ and $2^{\prime}-H\left(\delta_{H}=2.98\right)$ finally shows that a $\beta$-glucoside is involved.
The assignment of all of the chemical shift values and coupling constants as derived from the measurements can be checked in structural formula $\mathbf{D}$.

The natural product is the asperuloside described in the literature ${ }^{40}$. The assignments for the carbon pairs $\mathrm{C}-1 / \mathrm{C}-1{ }^{1}, \mathrm{C}-6$ / $\mathrm{C}-1$ and $\mathrm{C}-11 / \mathrm{CO}$ (acetyl) have been interchanged. Deviations of ${ }^{13} \mathrm{C}$ chemical shifts $\left(\mathrm{CDCl}_{3}-\mathrm{D}_{2} \mathrm{O}^{40}\right)$ from the values tabulated here $\left[\left(\mathrm{CD}_{3}\right)_{2} \mathrm{SO}\right]$ are due mainly to solvent effects. Here the difference between the measurements a and $\mathbf{d}$ shows that the use of $\mathrm{D}_{2} \mathrm{O}$ exchange to locate the OH protons where the CH COSY plot is available is unnecessary since OH
signals give no CH correlation signal. In this case $\mathrm{D}_{2} \mathrm{O}$ exchange helps to simplify the $\mathrm{CH}-\mathrm{OH}$ multiplets and so interpretation of the $H H$ COSY plot, which only allows clear assignments when recorded at 600 MHz .

## 46 Lacto-N-tetrose

The ${ }^{3} J_{H H}$ coupling constants $\left(8.2,8.0\right.$, and 8.4 Hz ) of the anomeric protons ( $1-H, \delta_{H}=5.14,4.57$, and 4.44) reveal a diaxial configuration of the protons attached to $\mathrm{C}-1$ and $\mathrm{C}-2$ in all pyranose units, reflecting three $\beta$-glycosidic linkages. The connectivities found in the HH COSY diagram a permit to distinguish between the four peracetylated sugar residues galactosyl ${ }^{1}$, galactosyl ${ }^{2}, 2-\mathrm{N}$ -acetylamino-2-deoxyglucopyranosyl- (GlcNac), and 2,3,6-tri-O-acetyl-sorbityl- (reduced glucopyranosyl):

$\beta$-D-galactopyranosyl-( $\mathrm{Gal}^{2}$ )

These assignments are confirmed by the $H H$ TOCSY diagram $\mathbf{b}$ and the selective one-dimensional experiment on top of $\mathbf{b}$ with the ${ }^{l} H$ NMR subspectrum of the 2- $N$-acetylamino-2-deoxygluco-pyranosyl- residue.
The sequence of the sugar units is deduced from the $H H$ ROESY in comparison with the $H H$ TOCSY plot. This is conveniently achieved by copying the ROESY experiment on transparent paper, putting both experiments one above the other and by looking for additional cross signals of the anomeric protons in the $H H$ ROESY. Additional cross signals (spatial correlations) of the anomeric protons are detected between $\delta_{H}=4.44 / 4.58\left(\mathrm{Ga1} 1^{1}-1-H / \mathrm{GlcNac}-3-H\right), 4.57 / 4.10$ $\left(\mathrm{Gal}^{2}-1-H /\right.$ Sorb-4-H), and $5.14 / 3.78\left(\mathrm{GlcNac}-1-H / \mathrm{Gal}^{2}-3-H\right)$.
To conclude, the sequence of sugars is Gal ${ }^{1}-\beta 1-3-\mathrm{GlcNac}-\beta 1-3-\mathrm{Gal}^{2}-\beta 1-4$-Sorbitol (peracetylated):

Additionally, all carbon-proton bonds can be assigned by means of the HC HSQC experiment $\mathbf{b}$ :

Finally, the structure of the original (genuine) tetrasaccharide (before acetylation and reduction) is $\mathrm{Gal}^{1}-\beta 1-3-\mathrm{GlcNac}-\beta 1-3-\mathrm{Gal}^{2}-\beta 1-4-\mathrm{Glc}$, known as Lacto- $N$-tetrose:

## 47 9-Hydroxycostic acid

In the ${ }^{1} H$ broadband decoupled ${ }^{13} \mathrm{C}$ NMR spectrum, 15 carbon signals can be identified, in agreement with the molecular formula which indicates a sesquiterpene. The DEPT experiments show that the compound contains four quaternary C atoms, three CH units, seven $\mathrm{CH}_{2}$ units and a $\mathrm{CH}_{3}$
group (Table 47.1); this affords the CH partial formula $\mathrm{C}_{15} \mathrm{H}_{20}$. Consequently, two H atoms are not linked to carbon. Since the molecular formula contains oxygen as the only heteroatom, these two $H$ atoms belong to OH groups (alcohol, carboxylic acid). The ${ }^{13} \mathrm{C}$ NMR spectrum shows a carboxy C atom ( $\delta_{\mathrm{C}}=170.4$ ). In the solvent $\left(\mathrm{CD}_{3} \mathrm{OD}\right)$ the carboxylic proton is not observed because of deuterium exchange. According to CH COSY and DEPT, the second OH group belongs to a secondary alcohol $(\mathrm{CHOH})$ with the shifts $\delta_{\mathrm{C}}=80.0$ and $\delta_{H}=3.42$ (Table 47.1).
In the alkene shift range, two methylene groups are found, whose CH connectivities are read off from the CH COSY plot (Table 47.1, $=\mathrm{CH}_{2}: \delta_{\mathrm{C}} / \delta_{H}=123.4 / 5.53 \mathrm{AB} 6.18$ and $=\mathrm{CH}_{2}: \delta_{\mathrm{C}} / \delta_{H}=$ 106.9/4.47 AB 4.65). The quaternary alkene C atoms to which they are bonded appear in the ${ }^{13} \mathrm{C}$ NMR spectrum at $\delta_{C}=146.9$ and 151.1 (Table 47.1). Because of the significant difference in the chemical shift values, one of the two CC double bonds ( $\delta_{\mathrm{C}}=123.4$ ) must be more strongly polarised than the other ( $\delta_{\mathrm{C}}=106.9$ ), which suggests that it is linked to the carboxy group ( $-M$ effect). The carboxy function and the two $\mathrm{C}=\mathrm{CH}_{2}$ double bonds together give three double-bond equivalents. In all, however, the molecular formula contains five double-bond equivalents; the additional two evidently correspond to two separate or fused rings.

Table 47.1. Intepretation of the $\mathrm{CH} \operatorname{COSY}$ plot ( CH bonds)

|  | $\delta_{\text {c }}$ | $\mathrm{CH}_{n}$ | attached proton(s) $\delta_{H}$ |

| CH partial formula |  | $\mathrm{C}_{15} \mathrm{H}_{20}$ |  |

Two structural fragments $\mathbf{A}$ and $\mathbf{B}$ can be deduced from the $H H$ COSY plot; they include the $A B$ systems of geminal protons identified from the CH COSY diagram (Table 47.1). Fragments A and $\mathbf{B}$ can be completed with the help of the CH data in Table 47.1.

The way in which $\mathbf{A}$ and $\mathbf{B}$ are linked can be deduced from the CH COLOC plot. There it is found that the C atoms at $\delta_{\mathrm{C}}=80.0(\mathrm{CH}), 49.8(\mathrm{CH}), 42.3(\mathrm{C})$ and $38.9\left(\mathrm{CH}_{2}\right)$ are separated by two or three bonds from the methyl protons at $\left(\delta_{H}=0.75\right)$ and thus structural fragment $\mathbf{C}$ can be derived.

In a similar way, the linking of the carboxy function with a CC double bond follows from the correlation of the carboxy resonance ( $\delta_{\mathrm{C}}=170.4$ ) with the alkene protons ( $\delta_{H}=5.53$ and 6.18 ); the latter give correlation signals with the C atom at $\delta_{\mathrm{C}}=38.5$, as do the protons at $\delta_{H}=1.33$ and 1.53 , so that taking into account the molecular unit $\mathbf{B}$ which is already known, an additional substructure $\mathbf{D}$ is established.
The position of the second CC double bond in the structural fragment $\mathbf{E}$ follows finally from the correlation of the ${ }^{13} \mathrm{C}$ signals at $\delta_{\mathrm{C}}=37.8$ and 49.8 with the ${ }^{1} H$ signals at $\delta_{H}=4.47$ and 4.65 . Note that trans protons generate larger cross-sectional areas than cis protons as a result of larger scalar couplings.

Table 47.2. Assembly of the partial structures $\mathbf{A}-\mathbf{E}$ to form the decalin framework $\mathbf{F}$ of the sesquiterpene

Table 47.2 combines partial structures $\mathbf{A}, \mathbf{B}, \mathbf{C}, \mathbf{D}$ and $\mathbf{E}$ into the decalin framework $\mathbf{F}$. The relative configurations of the protons can be derived from an analysis of ail the $H H$ coupling constants in the expanded ${ }^{l} H$ multiplets. The trans-decalin link is deduced from the antiperiplanar coupling ( 12.5 Hz ) of the protons at $\delta_{H}=1.33$ and 1.88 . The equatorial configuration of the OH group is derived from the doublet splitting of the proton at $\delta_{H}=3.42$ with 12.5 (anti) and 4.5 Hz (syn). In a corresponding manner, the proton at $\delta_{H}=2.60$ shows a pseudotriplet ( 12.5 Hz , two anti protons) of pseudotriplets ( 4.0 Hz , two syn protons), whereby the equatorial configuration of the 1-carboxyethenyl group is established. Assignment of all $H H$ couplings, which can be checked in Table 47.3 provides the relative configuration $\mathbf{G}$ of all of the ring protons in the trans-decalin. The stereoformula $\mathbf{G}$ is the result; its mirror image would also be consistent with the NMR data. Formula G shows the stronger shielding of the axial protons compared with their equatorial coupling partners on the same C atom and combines the assignments of all ${ }^{13} \mathrm{C}$ and ${ }^{1} H$ shifts given in Table 47.1. The result is the known compound $9 \beta$-hydroxycostic acid ${ }^{41}$.

Table 47.3. Relative configurations of the protons between $\delta_{H}=1.23$ and 3.42 from the $H H$ coupling constants of the expanded proton multiplets. Chemical shift values $\left(\delta_{H}\right)$ of the proton multiplets are given as large numerals in boldface and coupling constants $(\mathrm{Hz})$ are as small numerals

3.42 H

## 48 14-(Umbelliferon-7-O-yl)driman-3,8-diol

The given structure $\mathbf{A}$ is confirmed by interpretation of the CH COSY and CH COLOC diagrams. All of the essential bonds of the decalin structure are derived from the correlation signals of the methyl protons. In this, the DEPT subspectra differentiate between the tetrahedral C atoms which
are bonded to oxygen ( $\delta_{\mathrm{C}}=75.5$ : $\mathrm{CH}-\mathrm{O} ; 72.5: \mathrm{C}-\mathrm{O} ; 66.6: \mathrm{CH}_{2}-\mathrm{O}$ ). The methyl protons at $\delta_{H}=$ 1.19 , for example, give correlation maxima with the C atoms at $\delta_{\mathrm{C}}=72.5\left({ }^{2} J_{\mathrm{C} H}\right), 59.4\left({ }^{3} J_{\mathrm{C} H}\right)$ and $44.1\left({ }^{3} J_{\mathrm{CH}}\right)$. A corresponding interpretation of the other methyl CH correlations ( ${ }^{3} J_{\mathrm{CH}}$ relationships) gives the connectivities which are indicated in bold in structure $\mathbf{A}$. The assignment of $\mathrm{CH}_{2}$ groups in positions 2 and 6 remains to be established; this can be done by taking into account the deshielding ( $\alpha$ - and $\beta$-effects and the shielding $\gamma$-effects (as sketched in formulae $\mathbf{B}$ and $\mathbf{C}$ ).

A

$2 \alpha+3 \beta+5 \gamma$ effects
B

C

The assignment of the umbelliferone residue in $\mathbf{A}$ likewise follows from interpretation of the $J_{\mathrm{CH}}$ and ${ }^{2,3} J_{\mathrm{CH}}$ relationships in the CH COSY and CH COLOC plots following Table 48.1. The ${ }^{13} \mathrm{C}$ signals at $\delta_{\mathrm{C}}=112.9$ and 113.1 can be distinguished with the help of the coupled ${ }^{13} \mathrm{C}$ NMR spectrum: $\delta_{\mathrm{C}}=112.9\left(\mathrm{C}-3^{\prime}\right)$ shows no ${ }^{3} J_{\mathrm{CH}}$ coupling, whereas $\delta_{\mathrm{C}}=113.1\left(\mathrm{C}-6^{\prime}\right)$ shows a ${ }^{3} J_{\mathrm{CH}}$ coupling of 6 Hz to the proton $8^{\prime}-\mathrm{H}$.

a CH multiplicities from the DEPT ${ }^{13} \mathrm{C}$ NMR spectra.
b $A B$ systems of the protons attached to these $C$ atoms overlap.

Because of signal overcrowding in the aliphatic range between $\delta_{H}=1.3$ and 2.0, the $H H$ coupling constants cannot be analysed accurately. Only the deshielded $3-H$ at $\delta_{H}=3.39$ shows a clearly
recognisable triplet fine structure. The coupling constant of 2.9 Hz indicates a dihedral angle of $60^{\circ}$ with the protons $2-H^{A}$ and $2-H^{B}$; thus, $3-H$ is equatorial. If it were axial then a double doublet with one larger coupling constant (ca 10 Hz for a dihedral angle of $180^{\circ}$ ) and one smaller coupling constant ( 3 Hz ) would be observed.
The NOE difference spectra provide more detailed information regarding the relative configuration of the decalin. First, the trans decalin link can be recognised from the significant NOE of the methyl ${ }^{l} H$ signals at $\delta_{H}=0.80$ and 0.90 , which reveals their coaxial relationship as depicted in $\mathbf{D}$. For cis bonding of the cyclohexane rings an NOE between the methyl protons at $\delta_{H}=0.90$ and the cis bridgehead proton $5-H\left(\delta_{H}=1.49\right)$ would be observed, as $\mathbf{E}$ shows for comparison. An NOE between the methyl protons at $\delta_{H}=0.90$ and 1.19 proves their coaxial relationship, so the $8-\mathrm{OH}$ group is equatorial.

Further effects confirm what has already been established (5-H at $\delta_{H}=1.49$ cis to the methyl protons at $0.96 ; 3-H$ at $\delta_{H}=3.39$ cis to the methyl group at $\delta_{H}=0.80 ; 14-H^{A} H^{B}$ with $H^{4}$ at $\delta_{H}=4.13$ and $H^{B}$ at 4.37 in spatial proximity to the umbelliferone protons $6^{\prime}-H$ and $8^{\prime}-H$ at $\delta_{H}=6.80$ and 6.82). The natural product is therefore 14 -(umbelliferon-7-O-yl)-driman- $3 \alpha, 8 \alpha$-diol, $\mathbf{D}$, or its enantiomer.
Stereoformulae $\mathbf{F}$ (with ${ }^{I} H$ chemical shifts) and stereoprojection $\mathbf{G}$ (with ${ }^{13} \mathrm{C}$ chemical shifts) summarise all assignments, whereby equatorial protons exhibit the larger ${ }^{l} H$ shifts according to their doublet structure which can be detected in the CH COSY plot; equatorial protons, in contrast to their coupling partners on the same C atom, show only geminal couplings, and no additional comparable antiperiplanar couplings. The NOE difference spectra also differentiate between the $\mathrm{O}-\mathrm{CH}_{2}$ protons ( $\delta_{H}=4.13$ close to the coaxial methyl group at $0.90, \delta_{H}=4.37$ close to the methyl group at 1.19 as shown in $\mathbf{F}$ ).

## 49 3,4,5-Trimethyl-5,6-dihydronaphtho[2,3-b]furan

The molecular formula $\mathrm{C}_{15} \mathrm{H}_{16} \mathrm{O}$, which indicates a sesquiterpene, contains eight double bond equivalents; in the $\mathrm{sp}^{2}$ carbon chemical shift range ( $\delta_{\mathrm{C}}=107.5-154.4$ ) ten signals appear which fit these equivalents. Since no carboxy or carbonyl signals can be found, the compound contains five CC double bonds. Three additional double bond equivalents then show the system to be tricyclic.
In the ${ }^{13} \mathrm{C}$ NMR spectrum the large $\mathrm{C} I I$ coupling constant ( 197.0 IIz ) of the CH signal at $\delta_{\mathrm{C}}-$ 141.7 indicates an enol ether unit ( $=\mathrm{CH}-\mathrm{O}-$ ), as occurs in pyran or furan rings. The long-range quartet splitting ( ${ }^{3} ._{\mathrm{CH}}=5.9 \mathrm{~Hz}$ ) of this signal locates a $\mathrm{CH}_{3}$ group in the $\alpha$-position of this carbon atom. This structural element $\mathbf{A}$ occurs in furanosesquiterpenes, the furanoeremophilanes.

Starting from the five CC double bonds, three rings and a 3-methylfuran structural fragment, analysis of the CH COSY and CH COLOC diagrams leads to Table 49.1 and the identification of fragments $\mathbf{B}-\mathbf{J}$.
CH coupling relationships over two and three bonds (very rarely more) cannot always be readily identified. However, progress can be made with the help of the CH fragments which have been identified from the CH COSY plot, and by comparing the structural fragments $\mathbf{B}-\mathbf{J}$ with one another. One example would be the assignment of the quaternary C atoms at $\delta_{\mathrm{C}}=130.0$ and 133.2 in the fragments $\mathbf{G}$ and $\mathbf{H}$ : the weak correlation signals with the proton at $\delta_{H}=6.54$ may originate from CH couplings over two or three bonds; the correlation signal $\delta_{\mathrm{C}} / \delta_{H}=130.0 / 5.94$ clarifies this; the alkene proton obviously only shows CH relationships over three bonds, namely to the C atoms at $\delta_{\mathrm{C}}=130.0$ and 27.5.

The structural fragments $\mathbf{B}-\mathbf{J}$ converge to 3,4,5-trimethyl-5,6-dihydronaphtho[2,3-b]furan, $\mathbf{K}$. Whether this is the $5(S)$-or $5(R)$-enantiomer (as shown) cannot be decided conclusively from the NMR measurements. It is clear, however, that the $5-\mathrm{CH}$ proton at $\delta_{H}=3.36$ is split into a pseudoquintet with 7.1 Hz ; this is only possible if one of the $6-\mathrm{CH}_{2}$ protons (at $\delta_{H}=2.63$ ) forms a dihedral angle of about $90^{\circ}$ with the $5-\mathrm{CH}$ proton so that ${ }^{3} J_{H H} \approx 0 \mathrm{~Hz}$.

## 50 Sendarwine

The high-resolution molecular mass of the compound gives the molecular formula $\mathrm{C}_{21} \mathrm{H}_{28} \mathrm{O}_{6}$, which corresponds to eight double bond equivalents. The ${ }^{l} H$ broadband decoupled ${ }^{13} \mathrm{C}$ NMR spectrum shows a keto carbonyl group ( $\delta_{\mathrm{C}}=185.2$ ), two carboxy functions ( $\delta_{\mathrm{C}}=176.4$ and 170.4) and four further signals in the $\mathrm{sp}^{2}$ chemical shift range ( $\delta_{\mathrm{C}}=146.8,145.2,134.3$ and 120.9). These signals identify five double bonds. The three double bond equivalents still missing must then belong to three separate or fused rings. A complete interpretation of the CH COSY and DEPT experiments leads to the correlation Table 50.1 and to a CH partial molecular formula of $\mathrm{C}_{21} \mathrm{H}_{28}$, which shows that all 28 H atoms of the molecule are bonded to C atoms, and that no OH groups are present.

Table 50.1. Interpretation of the CH COSY plot and the DEPT spectra

| carbon atoms <br> $\delta_{\mathrm{C}}$ | multiplicity <br> 185.2 | $\mathrm{CH}_{n} \mathrm{a}$ |
| :---: | :--- | :--- | $\mathrm{CO}^{\mathrm{b}}$ attached protons

In the $H H$ COSY plot, structural fragment $\mathbf{A}$ can be identified starting from the signal at $\delta_{H}=4.88$. It is evident that two non-equivalent protons overlap at $\delta_{H}=1.95$. The CH COSY diagram (expanded section) shows that one of these protons is associated with the CH at $\delta_{\mathrm{C}}=44.1$ and the other with the methylene C atom at $\delta_{\mathrm{C}}=29.5$. Altogether the molecule contains two $\mathrm{CH}_{2}$ groups, identified in the DEPT subspectrum, whose methylene $A B$ protons can be clearly analysed in the $\mathrm{C} H$ COSY plot and which feature as $A B$ systems in the structural fragment $\mathbf{A}$.

Resonances in the $\mathrm{sp}^{2}$ carbon shift region provide further useful information: one at $\delta_{\mathrm{C}}=185.5$ indicates a keto carbonyl function in conjugation with a CC double bond; two others at $\delta_{\mathrm{C}}=176.4$ and 170.4 belong to carboxylic acid ester groups judging by the molecular formula and since OH groups are not present; four additional signals in the sp ${ }^{2}$ shift range ( $\delta_{\mathrm{C}}=146.8,145.2,134.3$ and 120.9) indicate two further CC double bonds, hence the ${ }^{l} H$ shift of $\delta_{H}=7.31$ and the CH coupling constant ( 202.2 Hz ) of the ${ }^{13} \mathrm{C}$ signals at $\delta_{\mathrm{C}}=145.2$ identify an enol ether fragment, e.g. of a furan ring with a hydrogen atom attached to the 2-position.
At this stage of the interpretation, the CH correlations across two or three bonds ( CH COLOC plot) provide more detailed information. The ${ }^{l} H$ shifts given in the CH COLOC diagram, showing correlation maxima with the C atoms at a distance of two to three bonds from a particular proton, lead to the recognition of eight additional structural fragments B-I (Table 50.2).

Table 50.2. Partial structures from the CH COLOC plot. Each partial structure $\mathbf{B}-\mathbf{I}$ is deduced from the two- or three-bond couplings $J_{C H}$ for the $H$ atoms of B-I (with italic $\delta_{H}$ values)

B

F

G

H

E

Whether the $C$ ' and $H$ atoms as coupling partners are two or three bonds from one another $\left({ }^{2} J\right.$ or ${ }^{3} J$ coupling) is decided by looking at the overall pattern of the correlation signals of a particular C atom with various protons. Thus for methyl protons at $\delta_{H}=1.08$, conrelation maxima for C atoms are found at $\delta_{\mathrm{C}}=54.9(\mathrm{CH})$ and 49.5 (quaternary C). The proton which is linked to the C atom at $\delta_{\mathrm{C}}=54.9\left(\delta_{H}=2.41\right.$, cf. CH COSY diagram and Table 50.1) shows a correlation signal with the methyl C at $\delta_{\mathrm{C}}=9.8$, which for its part is linked to the methyl protons at $\delta_{H}=1.08$. From this the fragment $\mathbf{G}$, which features parts of $\mathbf{C}$, follows directly. The combination of all fragments (following Table 50.2) then gives the furanoeremophilane skeleton $\mathbf{J}$ of sendarwine.

J

The relative configuration of the protons follows from the ${ }^{3} J_{H H}$ coupling constants, of which it is necessary to concentrate on only two signals (at $\delta_{H}=4.88$ and 2.41 ). The proton at $\delta_{H}=4.88$ shows a quartet with a small coupling constant ( 3 Hz ) which thus has no antiperiplanar relation-
ship to one of the vicinal protons; it is therefore equatorial and this establishes the axial position of the acetoxy group. The CH proton at $\delta_{H}=2.41$ shows an antiperiplanar coupling ( 9 Hz ) and a synclinal coupling ( 3 Hz ) with the neighbouring methylene protons. From this the relative configuration $\mathbf{K}$ or its mirror image is derived for the cyclohexane ring.

K

At first the configuration of the methyl groups at C-4a and C-5 remains unclear. The NOE difference spectra, which arise from the decoupling of various axial protons, provide the answer. Irradiation at $\delta_{H}=1.49$ leads to NOE enhancement of the coaxial protons (1.95 and 2.41) and of the cis protons ( $\delta_{H}=4.88$ ). Irradiation at $\delta_{H}=1.66$ has a strong effect on the methyl group at $\delta_{H}=$ 1.08, and from this the coaxial relationship of these protons in the sense of three-dimensional structure $\mathbf{L}$ is the result. Decoupling at $\delta_{H}=6.29$ induces strong effects on the coaxial protons at $\delta_{H}=1.95$ and 2.41 and weak effects on the obviously distant methyl groups ( $\delta_{H}=0.92$ and 1.08 ); irradiation at $\delta_{H}=2.41$ has a corresponding effect, producing a very distinct NOE at $\delta_{H}=6.29$ and a weaker effect at $\delta_{H}=1.49$ and 1.95 , because in these signals the effects are distributed among multiplet lines. From the coaxial relationships thus indicated the structure $\mathbf{L}$ (or its mirror image with cis methyl groups in positions 4 a and 5) is deduced.
L

The stereo projection $\mathbf{M}$ showing all ${ }^{l} H$ and ${ }^{13} \mathrm{C}$ signals summarises all assignments. Again it is evident that axial protons ( $a$ ) on the cyclohexane ring are more strongly shielded than their cqua torial coupling partners ( $e$ ) on the same C atom and that the diastereotopism of the isobutyric acid methyl groups is only resolved in the ${ }^{13} \mathrm{C}$ NMR spectrum.

Thus, sendarwine ${ }^{42}$ is systematically named as $6 \beta$-acetoxy- $4,4 a, 5,6,7,8,8 a, 9$-octahydro- $3,4 a \beta, 5 \beta$ -trimethyl-9-oxonaphtho[2,3-b]furan-4 $\beta$-yl-2-methylpropanoic acid ester.

## 51 Panaxatriol

The sample prepared is not particularly pure, so instead of the 30 signals expected, 33 signals are observed in the ${ }^{l} H$ broadband decoupled ${ }^{13} \mathrm{C}$ NMR spectrum. Only by pooling information from the DEPT experiment and from the CH COSY plot can a reliable analysis be obtained, as shown in Table 51.1. Here the $A B$ systems of the geminal $\mathrm{CH}_{2}$ protons are assigned.
The three $H$ atoms present in the molecular formula $\mathrm{C}_{30} \mathrm{H}_{52} \mathrm{O}_{4}$ but missing from the CH balance $\mathrm{C}_{30} H_{49}$ (Table 51.1) belong to three hydroxy groups.

Table 51.1. Interpretation of the DEPT spectrum $\left(\mathrm{CH}_{n}\right)$ and the CH COSY plot

Further information is derived from the NOE difference spectra with decoupling of the methyl protons. Table 51.2 summarises the most significant NOE enhancements to complete the picture.

Table 51.2. Interpretation of the NOE difference spectra

| Irradiation | significant nuclear Overhauser enhancement ( + ) |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

NOE enhancements (Table 51.2) reflect coaxial relationships between

- the $\mathrm{CH}-\mathrm{O}$ proton at $\delta_{H}=4.08$ and the $\mathrm{CH}_{3}$ protons at $\delta_{H}=0.92,0.97$ and 1.04,
- the methyl group at $\delta_{H}=0.88$ and the CH protons at $\delta_{H}=1.40$ and 3.50 ,
- the CH proton at $\delta_{H}=1.60$ and the $\mathrm{CH}_{3}$ protons at $\delta_{H}=1.04$ and 1.16,
as well as the cis relationship of the CH protons at $\delta_{H}=0.87$ and 3.15 with respect to the methyl group at 1.30 . From this the panaxatriol structure $\mathbf{A}$ is derived starting from the basic skeleton of dammarane.

The multiplets and coupling constants of the (axial) protons at $\delta_{H}=3.15,3.50$ and 4.08 moreover confirm the equatorial positions of all three OH groups, as can be seen in formula $\mathbf{B}$. Here the couplings from 10.0 to 11.5 Hz , respectively, identify vicinal protons in diaxial configurations, whilst values of 4.5 and 5.0 Hz , respectively, are typical for axial-equatorial relationships. As the multiplets show, the protons at $\delta_{H}=3.50$ and 4.08 couple with two axial and one equatorial proton (triplet of doublets) respectively, whereas the proton at $\delta_{H}=3.15$ couples with one axial and one equatorial proton (doublet of doublets).

Well separated cross signals of the $H H$ COSY plot demonstrate

- the geminal positions of the methyl groups at $\delta_{H}=0.97$ and 1.30 and
$\equiv$ the vicinal relationship of the protons at $\mathcal{S}_{H}=3.15-(1.55 A B 1.64), 1.60-3.50-(1.18 A B$ 1.90) and 0.87-4.08-(1.53 AB 1.55).

Those C atoms which are bonded to the protons that have already been located can be read from the CH COSY plot (Table 51.1) and thus partial structure $\mathbf{C}$ is the result.

The CH COLOC diagram shows correlation signals for the methyl protons which are particularly clear (Table 51.3). Interpretation of these completes the assignments shown in formula $\mathbf{D}$ by reference to those CH multiplicities which have already been established (Table 51.1).

Table 51.3. Interpretation of the CH COLOC diagram (methyl connectivities) using the CH multiplets derived from Table 51.1

| Methyl protons $\delta_{H}$ | C atoms separated by two or three bonds |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\delta_{C}$ | $\mathrm{CH}_{n}$ | $\delta_{\mathrm{C}}$ | $\mathrm{CH}_{n}$ | $\delta_{\mathrm{C}}$ | $\mathrm{CH}_{n}$ | $\delta_{C}$ | $\mathrm{CH}_{n}$ |
| 0.88 | 31.1 | $\mathrm{CH}_{2}$ | 41.0 | C | 48.7 | CH | 51.1 | C |
| 0.92 | 38.7 | $\mathrm{CH}_{2}$ | 39.2 | C | 49.4 | CH | 61.1 | CH |
| 0.97 | 30.9 | $\mathrm{CH}_{3}$ | 39.3 | C | 61.1 | CH | 78.5 | CH |
| 1.04 | 41.0 | C | 47.0 | $\mathrm{CH}_{2}$ | 49.4 | CH | 51.1 | C |
| 1.16 | 35.7 | $\mathrm{CH}_{2}$ | 54.7 | CH | 76.6 | C |  |  |
| 1.20 | 27.2 | $\mathrm{CH}_{3}$ | 36.5 | $\mathrm{CH}_{2}$ | 73.2 | C |  |  |
| 1.25 | 33.1 | $\mathrm{CH}_{3}$ | 36.5 | $\mathrm{CH}_{2}$ | 73.2 | C |  |  |
| 1.30 | 15.5 | $\mathrm{CH}_{3}$ | 39.3 | C | 61.1 | CH | 78.5 | CH |

Table 51.3 and formula $\mathbf{D}$ show that the methyl connectivities of the CH COLOC plot are sufficient to indicate essential parts of the triterpene structure.
Differentiation between the methyl groups at $\delta_{\mathrm{C}}=27.2$ and 33.1 and between the methylene ring C atoms at $\delta_{\mathrm{C}}=16.3$ and 25.2 remains. Here the $\gamma$ effect on the ${ }^{13} \mathrm{C}$ chemical shift proves its value as a criterion: C-23 is more strongly shielded ( $\delta_{\mathrm{C}}=16.3$ ) by the two axial methyl groups in $(\gamma)$ positions 20 and 25 of the tetrahydropyran rings than is $\mathrm{C}-16\left(\delta_{\mathrm{C}}=25.2\right)$. The axial $\mathrm{CH} H_{3}$ group at $\mathrm{C}-25$ is correspondingly more strongly shielded ( $\delta_{\mathrm{C}}=27.2$ ) than the equatorial (33.1), in accordance with the reverse behaviour of the methyl protons. Thus formula $\mathbf{E}$ is derived with its completc assignment of all protons and carbon- 13 nuclei.

## 52 trans-N-Methyl-4-methoxyproline

Rather large $H H$ coupling constants in the aliphatics range ( 12.5 and 15.0 Hz ) indicate geminal methyl protons in rings. In order to establish clearly the relevant $A B$ systems, it makes sense first to interpret the CH COSY diagram (Table 52.1). From this, the compound contains two methylene groups, $\mathbf{A}$ and $\mathbf{B}$.
$\begin{array}{ccc} & \delta_{H} & 2.34 A B 2.66 \\ \delta_{\mathrm{C}} & 38.2\end{array}$
B $\begin{array}{cc}\delta_{H} & 3.45 \mathrm{AB} 4.02 \\ & \delta_{\mathrm{C}} \\ & 754\end{array}$

Table 52.1. Intepretation of the CH COSY and the CH COLOC plots

| Partial structure | Protons |  | C atoms one bond $\delta_{C}$ | separated by two or three bonds |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\delta_{H}$ | $\mathrm{CH}_{n}{ }^{\text {a }}$ |  | $\delta_{\mathrm{C}}$ | $\delta_{C}$ |
|  | 4.58 | CH | 67.7 |  |  |
|  | 4.32 | CH | 77.8 | 170.6 |  |
| B | 3.45 AB 4.02 | $\mathrm{CH}_{2}$ | 75.4 | 67.7 |  |
|  | 3.40 | $\mathrm{OCH}_{3}$ | 55.0 | 67.7 |  |
|  | 3.15 | $\mathrm{NCH}_{3}$ | 49.1 | 77.8 | 75.4 |
| A | 2.34 AB 2.66 | $\mathrm{CH}_{2}$ | 38.2 | 77.8 |  |

a CH multiplicities from the coupled and DEPT ${ }^{13} \mathrm{C}$ NMR spectra.

Taking these methylene groups into account, interpretation of the HH COSY plot leads directly to the $H H$ relationships $\mathbf{C}$ even if the protons at $\delta_{H}=2.34$ and 4.58 do not show the expected cross signals because their intensity is spread over the many multiplet lines of these signals.

The $\mathrm{C} H$ COSY plot completes the $H H$ relationships $\mathbf{C}$ of the $\mathbf{C H}$ fragment $\mathbf{D}$ :

The typical chemical shift values and CH coupling constants in the one-dimensional NMR spectra reveal three functional grouns:

- $\quad N$-methylamino $\left(-\mathrm{NCH}_{3}, \delta_{\mathrm{C}}=49.1 ; \mathrm{Q}, J_{\mathrm{CH}}=144 \mathrm{~Hz} ; \delta_{H}=3.15\right)$,
- methoxy $\left(-\mathrm{OCH}_{3}, \delta_{\mathrm{C}}=55.0 ; \mathrm{Q}, J_{\mathrm{CH}}=146 \mathrm{~Hz} ; \delta_{H}=3.10\right)$,
- carboxy-/carboxamido- $\left(-\mathrm{COO}, \delta_{\mathrm{C}}=170.6\right)$.

If it were a carboxylic acid, the carboxy proton would not be visible because of deuterium exchange in the solvent tetradeuteriomethanol:

$$
-\mathrm{CO}_{2} \mathrm{H}+\mathrm{CD}_{3} \mathrm{OD} \rightleftharpoons-\mathrm{CO}_{2} \mathrm{D}+\mathrm{CD}_{3} \mathrm{OH}
$$

In the CH COLOC plot (Table 52.1) the correlation signals of the $\mathrm{N}-\mathrm{CH}_{3}$ protons $\left(\delta_{H}=3.15\right)$ with the terminal C atoms of the fragment $\mathbf{D}\left(\delta_{\mathrm{C}}=75.4\right.$ and 77.8 ) indicate an $N$-methylpyrrolidine ring E.

Since the carboxy-C atom in the CH COLOC diagram (Table 52.1) shows no correlation signal with the methoxy protons, it must be a carboxylic acid rather than a methyl ester. In the $\mathrm{CH} \mathrm{CO}-$ LOC plot of problem 53 there is, for example, a cross signal relating the carboxy-C atom with the $\mathrm{OCH}_{3}$ protons, because this compound is a methyl ester. Finally, a cross signal relating the carb-oxy-C atom ( $\delta_{\mathrm{C}}=170.6$ ) to the ring proton $2-H\left(\delta_{H}=4.32\right)$ in the CH COLOC plot locates the carboxy group on C-2. Hence the skeletal structure has been established; it is N -methyl-4-methoxyproline, $\mathbf{F}$.

The relative configuration is derived from the NOE difference spectra. Significant NOEs are detected owing to cis relationships within the neighbourhood of non-geminal protons:

$$
\delta_{H}=2.34 / 4.32 ; 2.66 / 4.58 ; 4.02 / 4.58 ;\left(\mathrm{NCH}_{3}\right) 3.15 / 4.02
$$

From this, the $N$-methyl and carboxy groups are in cis positions whereas the carboxy and methoxy groups are trans and so trans- $N$-methyl-4-methoxyproline, $\mathbf{G}$, is the structure implied. The NMR measurements do not provide an answer as to which enantiomer it is, $2 R, 4 S$ as shown or the mirror image $2 S, 4 R$.

The formulae $\mathbf{H}$ and $\mathbf{I}$ summarize the results with the complete assignments of all ${ }^{13} \mathrm{C}$ and ${ }^{1} \mathrm{H}$ chemical shifts ( $\mathbf{H}$ ) and the $H H$ multiplets and coupling constants (I). Herc the ${ }^{I} H$ multiplets which have been interpreted because of their clear fine structure are indicated by the multiplet abbreviation $d$ for doublet.

## 53 Cocaine hydrochloride

First the five protons (integral) of the ${ }^{l} H$ NMR spectrum ( $\delta_{H}=7.50-7.94$ ) in the chemical shift range appropriate for aromatics indicate a monosubstituted benzene ring with typical coupling constants ( 8.0 Hz for ortho protons, 1.5 Hz for meta protons.). The chemical shift values especially for the protons which are positioned ortho to the substituent ( $\delta_{H}=7.94$ ) reflect a $-M$ effect. Using the CH COLOC plot it can be established from the correlation signal $\delta_{\mathrm{C}} / \delta_{H}=166.4 / 7.94$ that it is a benzoyl group $\mathbf{A}$.

In the $H H$ COSY plot it is possible to take as starting point the peripheral $H$ signal at $\delta_{H}=5.59$ in order to trace out the connectivities $\mathbf{B}$ of the aliphatic $H$ atoms:

$$
\text { B } \quad \delta_{H} \quad 4.07 \rightarrow 2.44 \rightarrow 5.59 \rightarrow 3.56 \rightarrow 4.27 \rightarrow 2.51
$$

It is then possible to read off from the CH COSY plot those $\mathbf{C H}$ links $\mathbf{C}$ which belong to $\mathbf{B}$ and to see that between $\delta_{H}=2.22$ and 2.51 the protons of approximately three methylene groups overlap (integral). Two of these form $A B$ systems in the ${ }^{l} H$ NMR spectrum ( $\delta_{H}=2.24 A B 2.44$ at $\delta_{\mathrm{C}}$ 23.7; $\delta_{H}=2.22 A B 2.51$ at $\delta_{\mathrm{C}}=24.9$ ); one pair of the methylene protons approximates the $A_{2} \operatorname{system}\left(\delta_{H}\right.$ $=2.44$ at $\delta_{\mathrm{C}}=33.9$ ) even at 400 MHz .

The ${ }^{l} H$ and ${ }^{13} \mathrm{C}$ NMR spectra also indicate an $\mathrm{NCH}_{3}$ group ( $\delta_{\mathrm{C}} / \delta_{H}=39.6 / 2.92$ ) and an $\mathrm{OC}_{3}$ group $\left(\delta_{\mathrm{C}} / \delta_{H}=53.4 / 3.60\right)$. The CH connectivities $\mathbf{D}$ of the $\mathrm{NCH}_{3}$ protons $\left(\delta_{H}=2.92\right)$ across three bonds to the C atoms at $\delta_{\mathrm{C}}=65.3$ and 64.5 , derived from the CH COLOC plot, are especially informative, because the combination of $\mathbf{C}$ and $\mathbf{D}$ gives the $N$-methylpiperidine residue $\mathbf{E}$ with four spare bonds:
D

( $\delta_{C}:$ upight , $\delta_{H}:$ italics $)$
E

The CH COLOC diagram also shows

- the linkage $\mathbf{F}$ of the $\mathrm{OCH}_{3}$ protons $\left(\delta_{H}=3.66\right.$ ) with the carboxy C atom at $\delta_{\mathrm{C}}=174.1$,
- the connection $\mathbf{G}$ of the proton at $\delta_{H}=5.59$ with the same carboxy C atom,
- and the CH fragments $\mathbf{H}$ and $\mathbf{I}$ involving the protons at $\delta_{H}=4.07$ and 4.27;
if $\mathbf{B}$ and $\mathbf{C}$ are taken into account then the coupling partners $\left(\delta_{\mathrm{C}} / \delta_{H}=24.9\right.$ and 4.07 and $\delta_{\mathrm{C}} / \delta_{H}=$ 23.7 and 4.27 ) must be separated by three bonds.

F

G

H

1

Thus the ecgonin methyl ester fragment $\mathbf{J}$ can clearly be recognised; only the link to the $O$ atom still remains to be established. The attachment of the $O$ atom is identified by the large chemical shift value $\left(\delta_{H}=5.59\right)$ of the proton on the same carbon atom. The parts $\mathbf{A}$ and $\mathbf{J}$ then give the skeleton $\mathbf{K}$ of cocaine.

The fine structure of the ${ }^{l} H$ signal at $\delta_{H}=5.59(3-H)$ reveals the relative configuration of $\mathrm{C}-2$ and $\mathrm{C}-3$. A doublet ( 11.5 Hz ) of pseudotriplets $(7.0 \mathrm{~Hz}$ ) is observed for an antiperiplanar proton ( 11.5 Hz ) and two synclinal coupling partners ( 7.0 Hz ). From that the cis configuration of benzoyloxyand methoxycarbonyl groups is deduced (structure $\mathbf{L}$ ).
L

The orientation of the $\mathrm{NCH}_{3}$ group, whether syn or anti to the methoxycarbonyl function, is shown by the NOE difference spectrum in tetradeuteriomethanol. If the $N$-methyl proton ( $\delta_{H}=2.92$ ) is decoupled an NOE effect is obscrved for the protons at $\mathcal{S}_{H}=4.27,4.07$ and between $\delta_{H}-2.44$ and 2.51 but not merely at 2.44 . Thus, in tetradeuteriomethanol the $N$-methyl group is positioned anti to the methoxy carbonyl group. Hence the assignment of the endo and exo protons on C-6 and C7 in the structure $\mathbf{M}$ of cocaine hydrochloride can also be established.

CH multiplicities, CH coupling constants $(\mathrm{Hz})$, coupling protons

## 54 Viridifloric acid 7-retronecine ester (heliospathuline)

From the $H H$ COSY plot the $H H$ relationships A-D are read off:
A $\quad \delta_{H} \quad 4.43 \rightarrow 5.64 \rightarrow \begin{aligned} & 1.98 \mathrm{~A} \\ & 2.14 \mathrm{~B}\end{aligned} \underset{\substack{\text { a } \\ 3.49^{B}}}{2.60 \mathrm{~A}}$
B $\quad \delta_{H} \quad \begin{aligned} & 3.37 \mathrm{~A} \\ & 4.01 \mathrm{D}\end{aligned} \rightarrow 5.60 \rightarrow \begin{aligned} & 4.01 \mathrm{~A} \\ & 4.22 \mathrm{~B}\end{aligned}$
C $\delta_{H} \quad 3.85 \rightarrow 1.25$
D $\quad \delta_{H} \quad 0.73 \rightarrow 1.93 \rightarrow 0.85$

These can be completed following interpretation of the CH COSY diagram (Table 54.1) to give the structural fragments A-D.

The molecular formula contains four double-bond equivalents, of which the ${ }^{13} \mathrm{C}$ NMR spectrum identifies a carboxy group ( $\delta_{\mathrm{C}}=174.4$ ) and a CC double bond ( $\delta_{\mathrm{C}}=139.1$ : C , and $\delta_{\mathrm{C}}=124.3$ : CH with $H$ at $\delta_{H}=5.60$ from CH COSY) on the basis of the three signals in the $\mathrm{sp}^{2}$ chemical shift range. The two additional double-bond equivalents must therefore belong to two separate or fused rings. Since fragments $\mathbf{A}$ and $\mathbf{B}$ terminate in electronegative heteroatoms judging from their ${ }^{13} \mathrm{C}$ ( $\delta_{\mathrm{C}}=62.5,53.9$ and 76.3 ) and ${ }^{l} H$ chemical shift values (Table 54.1 ), a pyrrolizidine bicyclic sy-
stem $\mathbf{E}$ is suggested as the alkaloid skeleton, in line with the chemotaxonomy of Heliotropium species, in which fragments $\mathbf{A}$ and $\mathbf{B}$ are emphasised with bold lines for clarity.

Table 54.1. Intepretation of the CH COSY and the CH COLOC plots and the DEPT subspectra

| Partial structure | $\begin{gathered} \text { Protons } \\ \delta_{H} \end{gathered}$ | C a one bond $\delta_{C}$ | $\mathrm{nsse}$ <br> $\mathrm{CH}_{n}{ }^{\mathrm{a}}$ | ated two or ${ }^{\delta} \mathrm{C}$ | bonds $\delta_{C}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |

| $H$ atoms bonded to $\mathrm{C}: \mathrm{H}_{22}$ |  |  |  | ( therefore 3 OH ) |  |

a CH multiplicities from the DEPT ${ }^{13} \mathrm{C}$ NMR subspectra.

Correlation signals of the $A B$ systems $\delta_{H}=4.01^{A} 4.22^{B}$ and $3.37^{A} 4.01^{B}$ with the C atoms of the double bond (at $\delta_{C}=124.3$ and 139.1, Table 54.1) confirm the structural fragment B. A signal relating the proton at $\delta_{H}=5.64$ (Table 54.1 ) to the carboxy C atom (at $\delta_{\mathrm{C}}=174.4$ ) shows that the OH group at $\mathrm{C}-7$ has esterified (partial formula $\mathbf{F}$ ) in accord with the higher ${ }^{\prime} H$ shift (at $\delta_{H}=5.64$ ) of proton $7-\mathrm{H}$ caused by the carboxylate. When the OH group at $\mathrm{C}-7$ is unsubstituted as in heliotrin then $7-H$ appears at $\delta_{H}=4.06 .{ }^{31}$ On the other hand, the chemical shift values of the $A B$ protons at $\mathrm{C}-9$, which are considerably lower than those of heliotrin, indicate that the $9-\mathrm{OH}$ group is not esterified.

The relative configuration at C-7 and C-8 cannot be established from the $H H$ coupling constants; for five-membered rings the relationships between dihedral angles and coupling constants for cis
and trans configurations are not as clear as for six-membered rings. However, NOE difference spectra shed light on the situation: decoupling at $\delta_{H}=5.64$ ( $7-H$ ) leads to a very distinct NOE at $\delta_{H}$ $=4.43(8-H)$ and vice versa. The protons $7-H$ and $8-H$ must therefore be positioned cis $(\mathbf{G})$. Decoupling of $7-H$ also leads to an NOE on the protons $6-H^{A}$ and $6-H^{B}$, which indicates the spatial proximity of these three protons. A Dreiding model shows that the envelope conformation of the pyrrolidine ring ( $\mathrm{C}-7$ lies out of the plane of $\mathrm{C}-8, N, \mathrm{C}-5$ and $\mathrm{C}-6$ ), in fact places $7-\mathrm{H}$ between 6 $H^{4}$ and $6-H^{B}$ so that the distances to these protons do not differ substantially. The 7-H signal splits accordingly into a pseudotriplet with $3.5 \mathrm{~Hz} ; 8-H$ and $6-H^{4}$ are coupling partners of $7-H$ (dihedral angle ca $60^{\circ}$ ), whilst $6-H^{B}$ and $7-H$ have a dihedral angle of $90^{\circ}$ so no more couplings are detected.

Finally, fragments $\mathbf{C}$ and $\mathbf{D}$ belong to the acidic residues in the alkaloid ester. Taking into account the two OH groups (cf. Table 54.1), the CH correlation signal of the methyl protons at $\delta_{H}=0.73$ with the quaternary $\mathbf{C}$ atoms at $\delta_{\mathrm{C}}=83.9$ links $\mathbf{C}$ and $\mathbf{D}$ to the diastereomers viridifloric or trachelanthic acid; distinction between the two is discussed in more detail in the literature ${ }^{31}$. The diastereotopism of the isopropyl methyl C atoms is a good criterion for making the distinction. Their chemical shift difference is found to be $\Delta \delta_{\mathrm{C}}=17.2-15.7=1.5$, much closer to the values reported for viridifloric acid ester ( $\Delta \delta_{\mathrm{C}} \approx 1.85$; for trachelanthic acid ester a value of $\Delta \delta_{\mathrm{C}} \leq 0.35$ would be expected). Thus structure $\mathbf{H}$ of the pyrrolizidine alkaloid is established. It can be described as viridifloric acid-7-retronecine ester or, because of its plant origin, as heliospathuline ${ }^{45}$.

## 55 Actinomycin-D

2-Amino-4,6-dimethyl-3-oxo-3H-phenoxazine-1,9-dicarboxylic acid also named actinocin is the chromophor of the red antineoplastic chromopeptide actinomycin D (formula A). Two cyclopentapeptide lactone rings (amino acids: L-threonine, D-valine, L-proline, sarcosine, and $N$-methyl-Lvaline) are attached to the carboxy carbons of actinocin by two amide bonds involving the amino groups of threonine.

The attachment of the cyclopentapeptide lactone rings to the carboxy functions at C-1 and C-9 of the actinocin heterocycle $\mathbf{B}$ can be deduced from the HMBC plot d: Protons 7-H $\left(\delta_{H}=7.35\right)$ and $8-H\left(\delta_{H}=7.62\right)$ of the heterocycle display an $A B$ system in the proton domain. The attached carbon nuclei have been assigned by CH COSY in the literature $\left(\delta_{H} / \delta_{\mathrm{C}}=7.35 / 130.33\right.$ and 7.62/125.93, ref. ${ }^{6}$, p. 426); the other carbon atoms of the benzenoid ring within the phenoxazone are assigned as reported ${ }^{6}$ by correlation via ${ }^{2} J_{\mathrm{CH}}$ and ${ }^{3} J_{\mathrm{C} H}$ coupling detected in $\mathbf{d}$ which additionally shows a weak ${ }^{4} J_{\mathrm{C} H}$ correlation signal of $8-H$ with $\mathrm{C}-5 \mathrm{a}\left(\delta_{H} / \delta_{\mathrm{C}}=7.62 / 140.53\right)$.

Proton $8-H\left(\delta_{H}=7.62\right)$ gives a correlation signal via ${ }^{3} J_{\mathrm{CH}}$ coupling in the HMBC plot d with the carboxy carbon at $\delta_{\mathrm{C}}=166.18$ which also correlates with the $\mathrm{N} H$ proton of threonine at $\delta_{H}=7.15$. via ${ }^{2} J_{\mathrm{CH}}$. Starting with this proton, all protons in the cyclopentapeptide lactone ring attached to C-9 are assigned by means of the spatial correlation signals between the amino acid protons in the HH ROESY experiment (c) which occur in addition to the proton conncetivitics detected for the individual amino acids in the $H H$ COSY and $H H$ TOCSY ( $\mathbf{a}$ and $\mathbf{b}$ ). The latter permit the assignments of proton chemical shifts of all amino acid residues as outlined in Table 55.1, provided they are sufficiently resolved which is not the case for the $\alpha-, \beta$ - and $\gamma$-protons of $N$-methylvaline ( $\alpha-, \beta$-: $\delta_{H}=2.64-2.65, \gamma: \delta_{H}=0.82$ and 0.94 ) and the $N$-methyl protons of sarcosine ( $\delta_{H}=2.85$ ).

Table 55.1. Evaluation of $H H$ COSY and HH TOCSY for proton shift $\left(\delta_{H}\right)$ assignments of the amino acids

|  | Thr | Val | Pro | Sar | MeVal |
| :--- | :--- | :--- | :--- | :--- | :--- |
| NH | 7.15 | 8.00 |  |  |  |
| $\alpha-\mathrm{H}$ | 4.50 | 3.57 | 5.93 | 3.59 AB 4.78 | $2.04-2.65$ |
| $\beta-\mathrm{H}$ | 5.20 | 2.20 | 1.84 AB 2.93 |  | $2.64-2.65$ |
| $\gamma-\mathrm{H}$ | 1.24 | $0.88,1.11$ | 2.10 AB 2.26 |  | $0.82,0.94$ |
| $\delta-\mathrm{H}$ |  |  | 3.71 AB 3.82 |  |  |
| NCH |  |  |  | 2.85 | 2.89 |
| NH | 7.76 | 8.15 |  |  |  |
| $\alpha-\mathrm{H}$ | 4.61 | 3.53 | 6.00 | 3.62 AB 4.71 | $2.64-2.65$ |
| $\beta-\mathrm{H}$ | 5.15 | 2.13 | 1.80 AB 2.64 |  | $2.64-2.65$ |
| $\gamma-\mathrm{H}$ | 1.25 | $0.90,1.10$ | 2.04 AB 2.28 |  | $0.82,0.94$ |
| $\delta-\mathrm{H}$ |  |  | 3.70 AB 3.96 |  |  |
| NCH |  |  |  | 2.85 | 2.92 |

Evaluation of the $H H$ ROESY (c) verifies the amino acid sequence of the cyclopentapeptide lactone ring attached to $\mathrm{C}-9$ of actinocin by means of the NOE induced spatial correlation signals labelled ${ }^{\mathrm{a}-\mathrm{d}}$ in the formula $\mathbf{C}$. The $\alpha$ - and $\beta$-protons of threonine in both cyclopentapeptide lactone rings are sufficiently separated but close to each other. This applies to the other amino acid protons with the exception of $N$-methylvaline, in which proton signals overlap (Table 55.1). Therefore, starting from the $\alpha$ - and $\beta$-protons of threonine ( $\delta_{H}=4.61$ and 5.15), the sequence Thr-Val-Pro-Sar-MeVal attached to $\mathrm{C}-1$ of actinocin is similarly verified in the $H H$ ROESY as shown in formula C. The connection $\mathrm{Sar}-\mathrm{MeVal}$ is established by the spatial correlations ${ }^{\mathrm{d}}$ between the $B$ protons of sarcosine and the $N$-methyl-protons of $N$-methylvaline in both rings ( $\delta_{H}=4.71 / 2.92$ and 4.78/2.89).

The results of Table 55.1 complete the assignment of all proton shifts of both cyclopentapeptide lactones as far as possible as shown in formula $\mathbf{D}$.

Additional significant spatial correlations (NOE) in the HH ROESY experiment (c) provide information concerning the distances of some protons from one ring (at C-9) to the other (at C-1). Such closely spaced protons are:

$$
\begin{aligned}
& \operatorname{Pro}-\alpha(6.00)-\operatorname{Thr}-\alpha(4.61) ; \operatorname{Pro}-\alpha(5.93)-\operatorname{Thr}-\alpha(4.50) \\
& \text { Thr- } \alpha(4.61)-\operatorname{Pro}-\delta^{B}(3.90) ; \operatorname{Thr}-\alpha(4.50)-\operatorname{Pro}-\delta^{B}(3.82) \\
& \operatorname{Pro}-\delta(3.90)-\operatorname{Thr}-\mathrm{CH}_{3}(1.25) ; \operatorname{Pro}-\delta(3.82)-\operatorname{Thr}-\mathrm{CH}_{3}(1.24) \\
& \text { Thr-NH (7.76) }-\operatorname{Thr}-\mathrm{N} H(7.15)
\end{aligned}
$$

Molecular modelling calculations using values of smaller than 3 Angstrom units for these protonproton distances can be performed to obtain an optimized picture of the molecule. But this exceeds the scope of this book.

## SUBJECT INDEX

The abbreviations ( $\mathbf{F}, \mathbf{P}, \mathbf{T}$ ) are used to imply that the item referred to appears in Figures (spectra), in Tables or in solutions to Problems.

## A

Accumulation of FIDs 6
Acetals 11
diethyl- 55
Acetic acid
amide, $N, N$-dimethyl${ }^{1} \mathrm{H}$ NMR ( $\mathbf{F}$ ) 61
dichloro-, ethylester ${ }^{1} H$ NMR (F) 2
Acetophenone
2-hydroxy-(P) 192
Acetylacetone
hexafluoro1HNMR (F) 59
oxo-enol tautomerism ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR (F) 9
Acrolein
3-( $\mathrm{N}, \mathrm{N}$-dimethylamino)-(P) 189
3-amino-, ${ }^{1} H$ NMR (F) 6
Acrylic acid
ethylester ( $\mathbf{P}$ ) 180
Actinocin 246
Actinomycin D (P) 175, 246
Activation enthalpy
free molar 62
Aflatoxin B1 (P) 129, 219
Alanine
protonation 00
Alcohols
chiral 55
Aldehydes 11, 12, 27, 183, 184
$\alpha, \beta$-unsaturated 181, 189, 194, 212
Alkaloids 200, 243, 246
Alkenes 11, 46, 58, 180
cis- and trans-
${ }^{13} \mathrm{C}$ shitts 50
HH couplings 44
polarisation by substituents 14 , 181
Alkoxy groups 11
Alkyl groups 26
Alkynes 11, 58, 181, 197
Ammonia scale
of ${ }^{15} \mathrm{~N}$ shifts 14

Aniline
protonation 61
Anisotropy
effects on chemical shift 58
of molecular motion 66
Annulene(s)
[18]- 58
diaza[26]-59
Anthracene
dialdehyde, 1,8-(P) 184
Arabinopyranose 48
Aromatic compounds 11, 13, 14
Asperuloside ( $\mathbf{P}$ ) 224
B
Balance, CH 20
Benzaldehyde
3,4-dimethoxy-(F) 24
3-nitro-, ${ }^{1} \mathrm{H}$ NMR (F) 24
Benzene(s) 27
1,2-, 1,3- and 1,4-disubstituted
${ }^{1} H$ NMR (F) 23
1,2,3,4-tetrasubstituted 216
1,2,3-trisubstituted 183
1,2,4-trisubstituted 216
(F) 20
decamethylene-, 1,4-59
HH coupling constants 21
monosubstituted 66
p-disubstituted
$A A^{\prime} X X^{\prime}$ systems 4
ring current 58
Benzil
4,4'-dimethoxy-, 1HNMR (F) 24
Benzoic acid
4-amino-
7-( $N, N$-dimethylamino)ethy! ester hydrochloride
(P) 197
esters
conformation 51
phenylester 66
Benzoin
2-hydroxy-3,4-3; 4:-
tetramethoxy-(P) 215
Bifuran, 2,2'-
5,5'-bis-(hydroxymethyl)-
(P) 198

Biphenyl
2,2',6,6'-tetramethyl 67
Bonds
CC
from CC INADEQUATE 33
CH
from CH COSY, HC HSQC and HMQC 36
multiple
anisotropic effects 58
Broadband decoupling 7
But-1-en-3-yne cis-1-methoxy-(P) 181
Buta-1,3-diene cis-1-cyclopropyl-2-methyl-(P) 209
Butanol, 1CC INADEQUATE (F) 34

## C

Carbon atoms
primary, secondary, tertiary, quaternary 18
Carbon hybridisation influence on

CH coupiing ${ }^{1} \mathrm{~J}_{\mathrm{CH}} 26$
Carbonates 12
Carbonyl compounds 12,58 $\alpha, \beta$-unsaturated 51
Carboxylic acids 12
Carveol (P) 210
Catechol (P) 186
Chemical shitt(s) 1
influence of
anisotropic effects 58,184
aromaticity 11,58
concentration by
electronegativity (T) 12
mesomeric effects 14
protonation $(\mathrm{pH}) 60$
steric $(\gamma)$ effects
${ }^{13} \mathrm{C}(\mathrm{T}) 48,50$
temperature 61
of functional groups
${ }^{13} \mathrm{C}(\mathrm{T}) 12$
${ }^{15 N}(\mathrm{~T}) 14$
${ }^{1} \mathrm{H}(\mathrm{T}) 11$

Chirality 55
Cholesteryl chloride 65
Cinnamic acid, trans- 44
Clionasterol 55
Coalescence temperature 61, 189, 190
Cocaine hydrochloride (P) 243
Configuration
absolute 55
relative $42,44,46,48,50,186$ 187, 213
Conformation, conformers 54
${ }^{4} \mathrm{C}_{1}$ and ${ }^{1} \mathrm{C}_{4} 44,48$
anti and syn 42
Connectivities 6
${ }^{2} \mathrm{~J}_{\mathrm{CH}}$ and ${ }^{3} \sqrt{\mathrm{CH}}$, long range 39
CC 34
CH 36
HH 24, 30
Cope systems 62
Correlation spectroscopy
two-dimensional
CC 33
CH 36
HH 30
Correlation time 65
Costic acid
9ß-hydroxy (P) 228
Coumarin(s) 44, 231
3'4',6,7-tetramethoxy-3-phenyl- (P) 217
furo- 219
Coupling constants 2
and bonding type
CH -(T) 26
HH(T) 21
NH 205, 206
(T) 29
and conformation
CH-(3) 46
$\mathrm{HH} \cdot\left({ }^{(3}\right) 44$
and relative configuration
$\mathrm{CH}-(2 \mathrm{~J}, 3 \mathrm{~J}, \mathrm{~T}) 46$
$H H-(3, T) 42$
HH-( $\left.{ }^{2} \mathrm{~J}, \mathrm{~T}\right) 44$
NH -(2) 47
and substitution patterns
HH-
of aromatic and
heteroaromatic compounds ( $\mathbf{T}$ ) 21
influence of electronegativity
$\mathrm{CH}-\left({ }^{3}\right)$ ) 27,46
$\mathrm{HH}-\left({ }^{3}\right) 22$
Couplings
axial-equatorial, diaxial, diequatorial 44
cis and trans 44
endo-endo, exo-exo-, endo-exo44
geminal( ${ }^{2}$ ) 21
ortho, meta, para ( $3 \mathrm{~J}, 4 \mathrm{~J}, 5$ 5 $) 23$
vicinal ( ${ }^{3}$ ) 21
$w\left({ }^{4}\right) 21$
zig-zag ( $\sqrt[5]{ }$ ) 30
Cross signals 30
Cyanates 12
Cyanides (nitriles) 12
Cyclobutane(s) 26, 44
Cyclodecane 65
Cyclohexa-1,3-dien-5-ol-6-one
1,5-dimethyl-, dimer ( $\mathbf{P}$ ) 222
Cyclohexa-1,3-diene-
5-carboxylate
3-hydroxypropyl-2-ethyl- (P) 196
Cyclohexa-2,5-dienate
1-acetonyl-2,4,6-trinitro-,
potassium salt (P) 193
Cyclohexane(s) 58, 65
HH couplings 44
substituted
${ }^{13} \mathrm{C}$ shifts ( T ) 48
Cyclohexanol
3-methyl- and 4-methyl-cis- and trans- ( $\mathbf{T}$ ) 48
4--butyl-, cis- and trans${ }^{1} H$ and ${ }^{13} \mathrm{CNMR}(\mathbf{F}) 48$
trans-2-(2-pyridyl)methyl-(P) 212
Cyclohexene(s) 44,58
1,2-dimethyl-, cis-(P) 190
2-methyl-6-( $N, N$-dimethylamino)-trans-4-nitro-trans-5-phenyl(P) 189
cis-6-hydroxy-1-methyl-4-isopropyl- (P) 210
Cyclooctatetraene 58
Cyclopentane(s) 44
Cyclopentanol
trans-2-methyl- (P) 211
Cyclopentanone 12
Cyclopropane(s) $11,13,26,44$, 180
1,2-dicarboxylate, dimethyl, cis(P) 180
trans-1-isoprenyl- (P) 209
D
Decalin, trans- 229
DEPT subspectra (F) 19, 36
Deshielding 1
Deuterium exchange 12

(E)- and (Z)- 50

Hydrogen bonding
intermolecular 66
(F) 59
intramolecular 29, 193
(F) 60

I, J
Imidazole(s) 27
Imines 27, 47, 194
Indirect coupling 1
Inductive effects 12
Inversion
at amino nitrogen 62
Inversion-recovery
pulse sequence
for monitoring spin-lattice relaxation 63
Isocyanates 12
Isocyanide (isonitriles) 12
Isoflavone(s) 27
3; 4; 7,8-tetramethoxy- (P) 217
dimethyoxy-, 0,4'-(P) 105
Isopinocampheol
CC INADEQUATE (F) 35
DEPT subspectra (F) 20
Isoquinoline
$N$-methyl-6,7-methylenedioxy-1-oxo-1,2,3,4-tetrahydro-
(P) 200
$J$ coupling 2
K
Karplus-Conroy equation 42
Ketones 12
$L$
Lacto- N -tetrose ( $\mathbf{P}$ ) 226
Larmor frequency 1

## M

Meisenheimer salt (P) 193
Mesomeric effects 14

Methanol
${ }^{1} \mathrm{H}$ NMR ( $\mathbf{F}$ ) 59
Methoxy groups 11,12
Methyl groups 12 N-11, 243
Molecular dynamics (T) 62
Molecular formula from CH multiplicities 20
Monordene (P) 187
Motional narrowing 10
Multiplets 2
carbon-deuterium 7
carbon-proton 7
first and higher order 3
proton-proton 2
Multiplicity rules for first-order spectra 4
N
Naphthalene
HH coupling constants 21
Naphtho[2,3-b]furan
3,4,5-trimethyl-5,6-dihydro(P) 233

Nicotine
${ }^{13} \mathrm{C}$ spin-lattice relaxation (F) 67
NMR spectra
${ }^{13} \mathrm{C}$
proton coupled, NOE enhanced 19
proton decoupled 7
temperature dependent
(P) 190

1 H
temperature dependent
(F) 61
(P) 189

CW- and FT- 5
integrals 9
NO[ (nuclear Overhauser effect) 8
difference spectra 51,209
suppression 10
Nona-2-trans-6-cis-dienal ( $\mathbf{P}$ ) 213

Norbornene(s) 44
Nuclear precession 1

## 0

Octanol, 2-
${ }^{13} \mathrm{C}$ spin-lattice relaxation (F) 64
Oligosaccharides (P) 138, 225
Oxirane(s) 26
methyl-(P) 187
$P$
Panaxa-3 $3,6 \alpha, 12 \beta$-triol ( $\mathbf{P}$ ) 239
Pascal triangle 4

Pentanedione, 2,4-
oxo-enol tautomerism ${ }^{1 H}$ and ${ }^{13} \mathrm{CNMR}(\mathbf{F}) 9$
Peptide
sequencing 175, 247
Phenol(s) 183 o-nitro-, 1 HNMR (F) 23
Phenones 192
conformation 51
Phthalide
hydroxy-(P) 207
Pinene, $\alpha$ -
CH COLOC (F) 40
$\mathrm{CH} \operatorname{COSY}(\mathbf{F}) 36$
DEPT subspectra (F) 19
HC HMBC (F) 40
HC HSQC (F) 36
HH COSY, HH TOCSY (F) 33
HH NOESY (F) 53
HH ROESY (F) 53
$J$-resolved ${ }^{13} \mathrm{C} \operatorname{NMR}(\mathbf{F}) 19$
NOE difference spectra (F) 51
Population
of conformers $42,48,54$
Porphyrin(s) 59
2,3-diaza-7,8,12,13,17,18-hexaethyl-(P) 214
Praseodymium(III) chelates chiral shift reagents 56
Procaine hydrochloride (P) 197
Prochirality 55
Proline
trans- N -methyl-4-methoxy(P) 241

Propenal 3-[4-N,N-dimethylamino)phenyl]-2-ethyl, trans- (P) 194
trans-3-N-methylpyrrol-2-yl(P) 181

Proton decoupling
heteronuclear broadband 7 gated 8 inverse gated 10 solective 7
homonuclear 6
Pulegone 58
Puise interíerogram 5
Pyranosides 46
${ }^{13} \mathrm{C}$ shiffs (T) 48
HH couplings 44
Pyrazole
5-hydroxy-3-methyl-1H(P) 192

Pyridine(s) 11, 13, 27, 61, 182
2-p-tolylsulphonyl-5-propyl- (P) 202
3-acetyl-(P) 182

3-bromo-, HNMR (F) 25
5-ethynyl-3-methyl- (P) 191
HH coupling constants 22
NH coupling constants 29
Pyrimidine(s) 27
2,4,6-trichloro-, ${ }^{13} \mathrm{C}$ NMR (F) 8
2-azido-5-n-butyl- (P) 205
tetrazolo[1,5-a]-6-n-butyl- (P) 205
triazolo[1,5-a]-(P) 205
Pyrone(s) 27
Pyrrole(s) 11, 13, 27, 181, 182
2-ethoxycarbonyl-
4-(3-hydroxypropyl)-Nmethyl ( $\mathbf{P}$ ) 201
HH coupling constants 22
NH coupling constants 29
Pyrrolizidine 246
Pyrromethene
1,9-bis(pyrrol-2-y)-(P) 182
Q
Quantitative analysis
by NMR 9, 206
Quinoline
HH COSY (F) 30
Quinones 12

## R

Rate law
first-order 62
Relaxation
spin-lattice and spin-spin 10
Relaxation times
spin-lattice 10,63
spin-spin 10
Ring current 58
Ring inversion
of cyclohexanes 62, 190
Roofing (AB effect) 4, 180
Rotation
hindered 61
by hulky substituents 6 ?
unimpeded free 42,43

## S

Salicylaldehyde 29,60
Salicylaldimine
N-butyl-(P) 194
Scalar coupling 1
Segmental mobility 66
Sendarwine (P) 236
Shielding 1
Shift reagents
chiral 56
Shift(s), chemical 1
influence of
anisotropic effects 58
aromaticity 11,58
concentration 59
electrongativity ( $\mathbf{T}$ ) 12
mesomeric effects 14, 184
protonation (pH) 60
steric ( $\gamma$ ) effects
${ }^{13} \mathrm{C}(\mathrm{T}) 48,50$
temperature 61
of functional groups
${ }^{13} \mathrm{C}(\mathrm{T}) 12$
${ }^{15} \mathrm{~N}(\mathrm{~T}) 14$
${ }^{1} \mathrm{H}(\mathrm{T}) 11$
Signal multiplicity 2
$\mathrm{CH}_{n}$
determination 18
HH
translation to structural units 16
Sitosterol 55
Solvation 59, 199
diastereomers 56
Solvents
chiral 56
Spin decoupling 6
Spin quantum number and signal multiplicity 4
Spin systems
(AB) ${ }_{2} \mathrm{C} 54$
$A_{2} X_{2} 199$
$A_{3} X_{2} 180$
AA ${ }^{\prime} X^{\prime}$ 5, 24, 184, 185
AB 4, 16
ABM 186
ABX 185
AMX 6, 25, 183
AMX2 180
$A_{m} X_{n} 3,16$
AX 3, 16
Spin systems (F) 16
Spin-lattice relaxation ( ${ }^{13} \mathrm{C}$ )
dipolar mechanism 6 b
influence of
molecular motion 65
molecular size 65
number of bonded protons
65
segmental mobility 66
influence on NOE 65
Spin-spin coupling
${ }^{1 J},{ }^{2} \mathrm{~J},{ }^{3} \mathrm{~J},{ }^{4} \mathrm{~J} 2$
scalar and dipolar 1
Steric ( $\gamma$ ) effects 12
Stilbene
aldehyde, trans-4-(P) 184
Structure elucidation
by NMR, tactics 67
Styrene
3,4-dimethoxy- $\beta$-methyl $-\beta$-nitro-
${ }^{13}$ C NMR (F) 27

Substituent effects
alkyl ${ }^{13} \mathrm{C}$ shifts 14
benzenoid ${ }^{13} \mathrm{C}$ shifts 14,197

+ and -M 14, 192
- 12

Substitution patterns
from multiplicities and
coupling constants 21
T
Tautomerism 9, 192, 214
Terpenes
mono- 210, 224
sesqui- 226, 231, 232, 235
tri- 239
Tetralin-1-one
6-methoxy-(P) 204
Thiocyanates 12
Thiophene(s) 11
HH coupling constants 22
TMS (tetramethylsilane)
scale of ${ }^{1 H}$ and ${ }^{13} \mathrm{C}$ shifts 1
standard substance 1
Two-dimensional NMR
CC INADEQUATE
symmetrised (F) 34
CHCOLOC (F) 39
$\mathrm{CH} \operatorname{COSY}(\mathbf{F}) 36$
HC HMBC (F) 39, 122, 178
HC HMQC and HSQC (F) 36
HC HSQC (F) 121, 139
HH COSY (F) 30
HH NOESY (F) 53
HHROESY (F) 53, 141, 177
HH TOCSY (F) 33, 141, 176
$J$-resolved ${ }^{13} \mathrm{C}(\mathbf{F}) 19$
stacked and contour plots 30
U
Umbelliferone derivatives 231
Uncertainty principle 59
Ureas 12

## V,W

Valence isomerism 205
Valence tautomerism 62
Valine 55
Van der Waals interaction 50
Viridifloric acid-7-retronecine
ester (P) 246
w-coupling ( ${ }^{4}$ ) 21
$X, Y$
Xylenol, 2,6-
metabolite (P) 130, 220
Xylopyranose 48
Z
Zero intensity interval
in $T_{1}$ measurements 64
